Tests and studies of the double-winding generator have shown that, in addition to being able to transfer through the unit from one section to another and to generate in either winding almost irrespective of the load carried by the other winding, one can vary the voltage of either winding of the unit to a certain extent by varying the field current. In fact, it is even possible to produce a lower terminal voltage on an unloaded winding than on a loaded winding by under-exciting the field when the unit is tied into such a bus arrangement as is shown in Fig. 23.

STATEMENT BY THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY

Structural Steel and Welding

The present tendency in the design of generators is toward the more general use of structural steel and fabricated construction. Such material is inherently more suitable than that used in the older designs, due to its absence of flaws and to its uniformity of strength. In fact, its strength and permissible working stresses are quite accurately known, whereas with cast material much dependence must be placed upon the soundness of the casting, which is, unfortunately, a more or less indeterminate factor. Furthermore, the use of fabricated construction has materially increased production, because there has been an elimination of large patterns and a reduction in the amount of machining required, and also because standard structural-steel sections, which are used to a great extent, can be kept in stock.

In the early designs of steam-turbine-driven generators, the frames were made of cast iron and, because the casting included the ducts for conducting the cooling air to and from the core, the frame widths became too great for shipment with the usual railroad clearances. The excessive weight involved is another objection to the cast frame. These objections led to the separation of the frame into two parts; a superstructure of light structural steel for the air passage and a skeleton frame for carrying the core.

This improvement in stator construction has resulted in such designs that the heaviest pieces to be shipped weigh approximately 30 per cent less than formerly, and the weights of the installed stators are approximately 15 per cent less. A similar improvement, leading to the construction of structural-steel skeleton frames, has decreased the stator weight for a given capacity by another 10 per cent, and has raised the capacity limit of machines which can be built and wound at the factory from 75,000 kv-a. to approximately 100,000 kv-a. A frame of the older type is shown in Fig. 25, whereas the skeleton-frame construction is illustrated in Fig. 26.

The use of structural steel for frames and similar parts is a logical extension of the practice of using rolled plate or laminated construction in the rotors of all the more important generators which have been built. The uniform structure of the material can be depended upon and, where this characteristic is essential, complete satisfaction cannot be obtained with castings. The inherent limitations in the use of castings for rotating parts has long been recognized, and in the past their application to such parts has been made chiefly in low-speed machines.

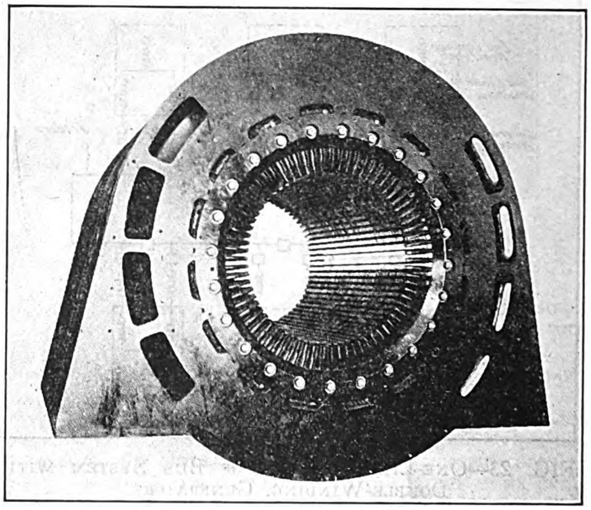

FIG. 25—WESTINGHOUSE FRAME USED IN THE OLDER TYPE OF GENERATOR.

During the past year, fabricated construction has been adopted for the standard lines of moderate-size low-speed horizontal and vertical synchronous motors and generators, general-purpose synchronous motors and the corresponding sizes of generators, direct-current generators and motors, and 3600-r.p.m. steam-driven turbo-generators. The full benefits of the fabricated construction have been obtained through complete redesign of the lines of machines in question.

Several illustrations may be given of present designs employing structural steel. A 7500-kv-a., 225-r.p.m. vertical waterwheel generator built for the city of Eugene, Ore., is of particular interest in that it is built entirely of fabricated material; the frame, the upper bracket and the lower bracket are of structural steel, and the rotor consists of a steel rim and I-beam spokes. The Aluminum Company of America has recently ordered two 45,000-kv-a., 150-r.p.m. vertical waterwheel generators, each of which will be built with a structural-steel frame and a structural-steel lower bracket; the rotor will be built of structural arms and hubs and a laminated rim. For the W. S. Barstow Management Corporation's Saluda River development, the four 40,625-kv-a., 138-r.p.m., vertical waterwheel generators will be unique in that they will be of the umbrella type, with only one guide and one thrust bearing, mounted below the rotor, from the lower bracket; the usual upper bracket will not be furnished, although a support for the direct-connected exciter will be necessary. The umbrella machines will have a structural frame and a structural lower bracket, but the

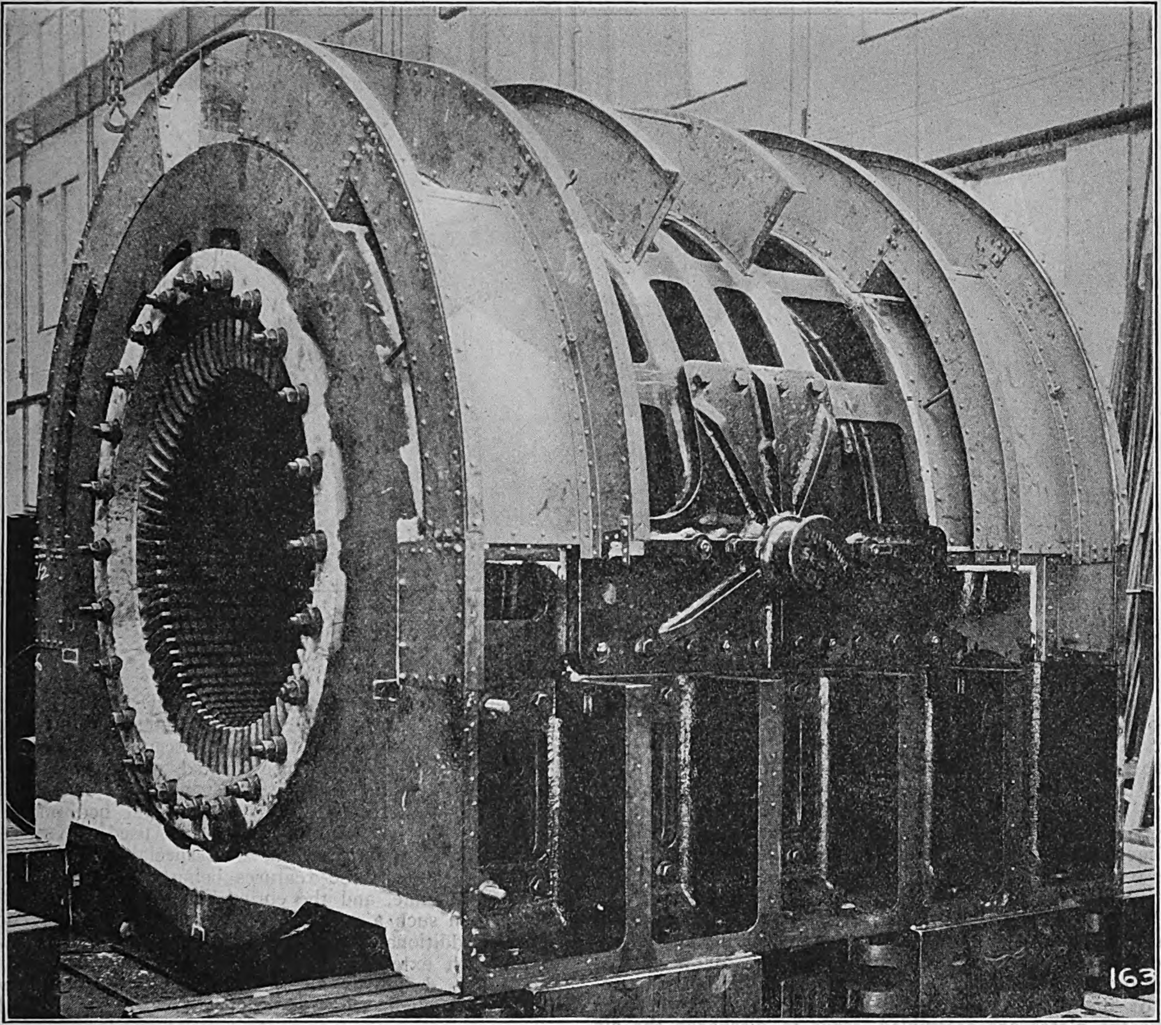

FIG. 26—WESTINGHOUSE SKELETON-FRAME CONSTRUCTION USED ON THE NEWER TYPE OF GENERATOR.

rotor will be of the cast-steel center-laminated-rim type; no oiling system will be required, since the thrust bearing and the guide bearing will operate in a floor of oil.

During the past year, there has been brought out a new line of low-speed vertical waterwheel generators employing fabricated construction throughout, the line including ratings of from 62½ kv-a. to 3000 kv-a. For this line the construction of fabricated frames is illustrated in Fig. 27; fabricated lower brackets, in Fig. 28; fabricated upper brackets, in Fig. 29; and built-up rotors, in Fig. 30. The rotors of this new line will consist for the most part of either cast-steel or forged-steel rims shrunk onto the structural-steel spider, with sufficient pressure to withstand the centrifugal forces obtained at the required overspeeds; the rims are either rim-keyed or welded to the spiders. Fig. 31 shows a 2000-kv-a., 180-r.p.m. vertical waterwheel generator for the Central Power & Light Company, and Fig. 32, a 100-kv-a., 450-r.p.m. machine for the Wisconsin Power & Light Company.

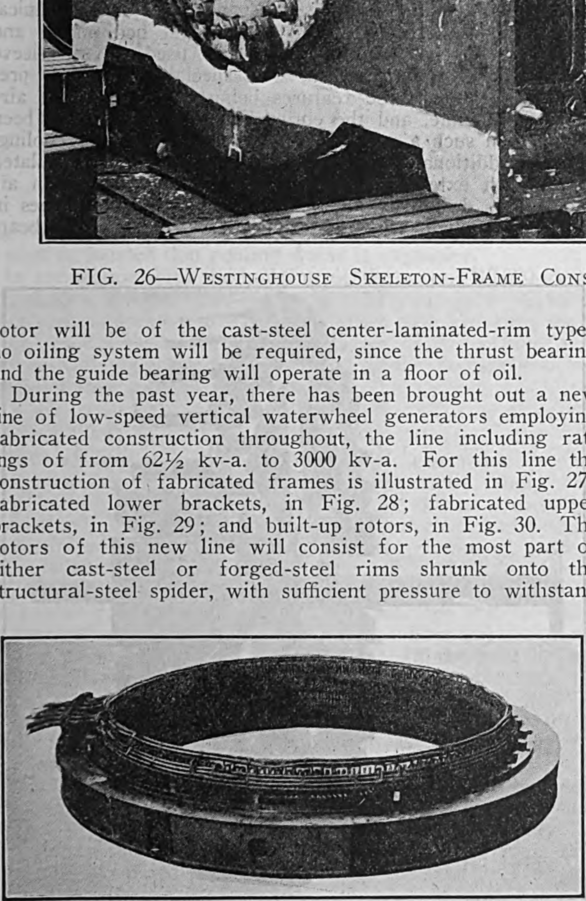

FIG. 27—FABRICATED FRAME OF WESTINGHOUSE VERTICAL WATERWHEEL GENERATOR.

Other Mechanical Advances

Size Considerations

The size of machines is increasing from year to year in order to satisfy the needs of the industry. The largest machines so far constructed, from the point of view of physical dimensions, are the 40,000-kv-a., 81.8-r.p.m. vertical waterwheel generators at the Conowingo Station of the Philadelphia Electric system. The largest steam-turbine generators constructed to date are the two 94,000-kv-a., 1800-r.p.m. machines comprising the cross-compound unit for the Hell Gate Station of the United Electric Light & Power Company. There has also been completed a 12,500-kv-a., 3600-r.p.m. steam-turbine generator with shaft fans of novel design. Three 30,000-kv-a. synchronous condensers have been built for operation at 720 r.p.m.

The Conowingo generators are, as previously stated, physically the largest generators ever constructed, each machine having a weight of approximately 1,140,000 lb. and an overall diameter of approximately 37 ft. Each unit is complete with an auxiliary shaft alternator, which furnishes power to a motor-generator set, which in turn furnishes the

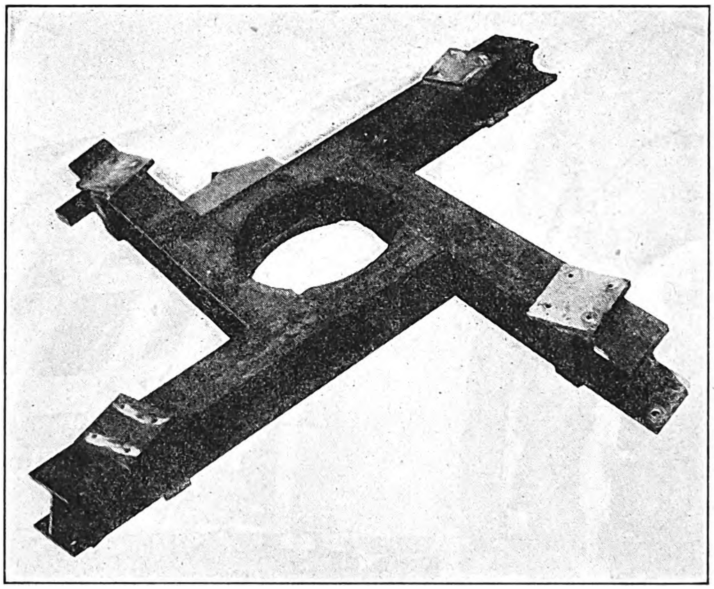

FIG. 28—FABRICATED LOWER BRACKET OF WESTINGHOUSE VERTICAL WATERWHEEL GENERATOR.

excitation for the main alternator. The auxiliary alternator is excited by means of a small direct-connected exciter.

The rotor construction of the large 1800-r.p.m. machines, as in the past, is of built-up plate. On the largest machines built, however, the rotor plates have a large central bore, possible only in rotors of this construction, such an arrangement providing greater facility for rotor cooling. A cross-section through one of the largest generators, showing the modified system of ventilation, is illustrated in Fig. 33. Oblique holes, drilled in the shaft ends before assembly with the plates, carry a portion of the cooling air to the center of the rotor. The remainder of the air is carried through the teeth by means of axial holes in the end portion of the rotor. Radial slots, cut into each rotor tooth before the plates are assembled, serve to discharge the air from the center of the rotor. Fig. 34 shows the rotor of a 94,000-kv-a. machine of the hollow-plate construction.

The 12,500-kv-a., 3600-r.p.m. steam-turbine generator referred to was built for the Kansas City Power & Light Company. A shop view of this machine is shown in Fig. 35. The machine has self-contained fans of novel design, the measured fan efficiency being 43 per cent, double the efficiency of any shaft fans previously designed to meet the difficult conditions imposed by large 3600-r.p.m. generators.

During the past year there has been developed a new line of synchronous condensers rated at from 500 kv-a. to 30,000 kv-a., embodying the latest practices in mechanical construction. Structural-steel frames and bed plates, and laminated punched rotor centers are used. New sleeve bearings have been designed, with special features to prevent oil leakage, these features being based upon the air-by-pass principle, and the entire line of bearings has been designed in such a manner as not to require water cooling. In case additional cooling is required, the oil is circulated through an external cooler, located in the foundation air duct. This design avoids the use of water-cooled pipes in the bearing shell, which, in some cases, have led to bear-

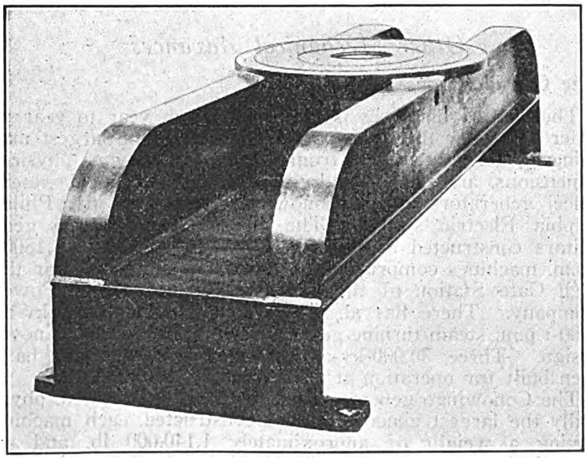

FIG. 29—FABRICATED UPPER BRACKET OF WESTINGHOUSE VERTICAL WATERWHEEL GENERATOR.

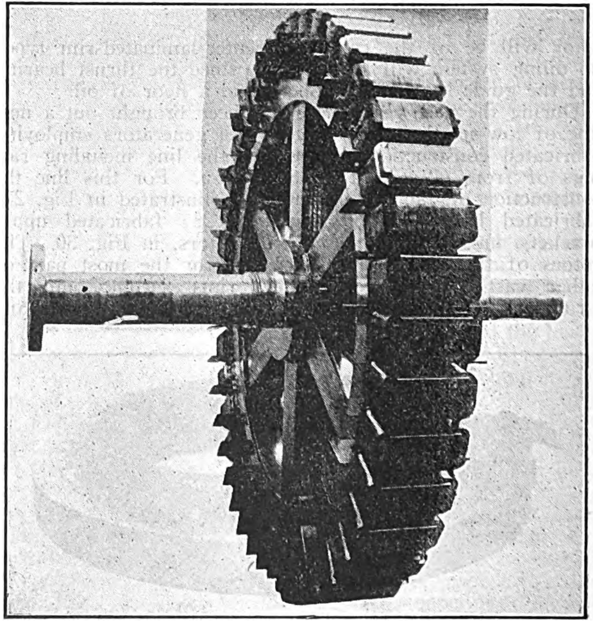

FIG. 30—BUILT-UP ROTOR OF WESTINGHOUSE VERTICAL WATERWHEEL GENERATOR.

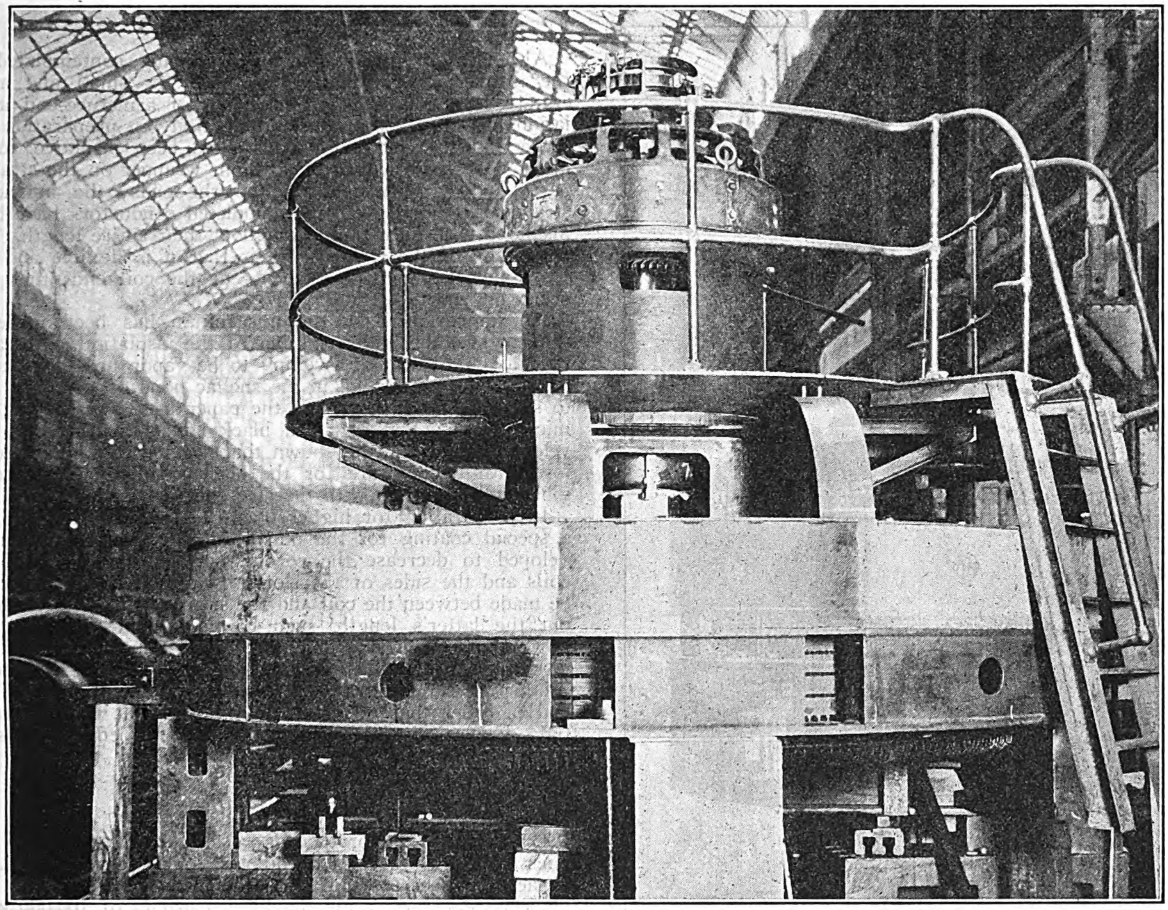

FIG. 31—2000-KV-A. WESTINGHOUSE VERTICAL WATERWHEEL GENERATOR FOR THE CENTRAL POWER & LIGHT COMPANY.

ing failures, and is of particular importance in the substation so located that cooling water is expensive.

In connection with the building of the second 40,000-kv-a. frequency-converter set for the Commonwealth Edison Company, a frame-shifting device of a new hydraulic type is being developed. This device consists of two pistons and hydraulically connected cylinders, with the necessary pressure-applying equipment.

Lubrication System

Several improvements have recently been made in the design of bearings and in the arrangement of oiling systems in order to lengthen the life of the oil, to reduce the amount of leakage and otherwise to improve lubrication. These improvements may be said to have eliminated certain oiling difficulties which are experienced in operation and which may largely be attributed to two principal causes, viz., the drawing of oil vapor out of the bearings and oil fans by suction created by the rotor, and the flow and creepage of any excess oil fed to the bearings. In the past it has been necessary to adjust the oil flow to the bearings to almost the exact amount required, i.e., sufficient oil had to be supplied adequately to lubricate the bearings but no excess could be permitted since such excess would be likely to overflow and to find its way into the machine itself.

The so-called pressure overflow system has been developed to remedy the difficulties experienced with the old method of lubrication, and is shown diagrammatically in Fig. 36. In the new system, the oil is discharged from the pump and is carried to a header, where the feed lines to the various bearings are connected. In the header is a pressure-relief valve adjustable for pressures of from two to ten pounds per square inch, the arrangement being such that any pressure between these limits can be maintained practically constant at the point where the three connections for the bearing feeds are made and the oil flow to individual bearings is therefore not influenced by the adjustment of oil flow to any other bearing. It can readily be seen that, if more oil should be fed to one of the bearings than to either of the others, less oil would overflow to the relief valve and the pressure at the point where the feed lines are connected would therefore remain practically unchanged. In addition to the fact that vapor formation and oil creepage are practically eliminated by the new oiling system, there is the marked advantage that oil will be delivered to the bearings, as the generator is started from rest, much sooner than with the old system.

In the new system, overflow connections have also been provided at the top of each guide bearing. These connections permit excess oil to be supplied to each bearing as an assurance of adequate lubrication, but without any danger of flooding the machine.

It has been customary in the past to return the oil from the upper guide bearing directly to the lower oil pan, through pipes in the rotor, with a consequent tendency, due to the rotation of these pipes, for the production of vapor where the oil would be discharged from the pan. The present practice is to provide a stationary oil pan beneath the upper guide bearing, from which a drain is connected to the lower pan.

Outdoor Generators

Some attention in recent years has been given to so-called outdoor generators. So far as the generator itself is concerned, investigation seems to indicate that there is little in the requirements for this service necessitating modification of the present type of construction. Generators of standard construction, but with housings for protection and ventila-

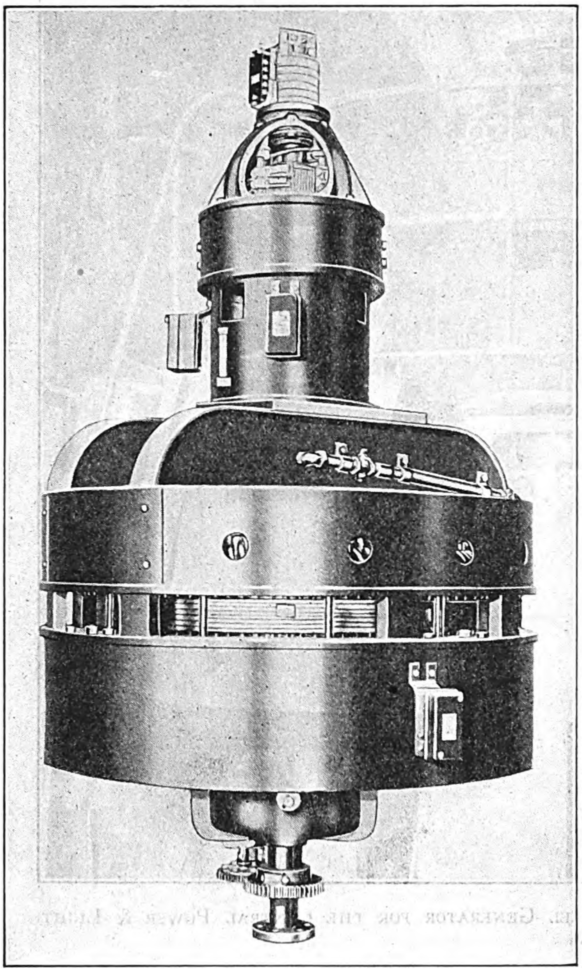

FIG. 32—100-Kv-a. Westinghouse Vertical Waterwheel Generator for the Wisconsin Power & Light Company.

tion, have been installed in a number of instances. These may be more logically termed semi-outdoor installations, and actually represent no departure from ordinary practice insofar as generator design is concerned. The novelty is found in the reduction of the building to the simplest structure, location being permitted in the dam or other advantageous place. Such an installation is shown in Fig. 37. It has even been proposed that the usual frame be omitted and the various parts of the generator built into and supported by the concrete foundations. There is little merit in this scheme, since some supporting structure for the stator punchings would be necessary in any event and since the problem of alignment would be extremely difficult of solution.

Power-Operated Brakes

Power-operated brakes are occasionally installed in connection with automatically controlled waterwheel generators. The value of brakes appears to lie principally in the assurance that the waterwheel will be brought to a complete stop when not delivering power. Water leakage sometimes causes rotation in reaction-wheel installations and, under such conditions, the brake will prevent useless wear and tear or bring the unit to rest for inspection or repair. The necessity for the extra expense and complication of brakes is much reduced when leakage can be controlled. There appears to be little excuse for the use of brakes where the driving force can be positively removed, as it can in the case of impulse-wheel installations.

Insulating Compounds

Although no major changes are being contemplated in the insulation of armature windings for small and moderately sized machines, the question of armature-coil insulation has been given considerable study in preparation for larger units. The stator coils have been insulated for a number of years with a micafolium wrapper on the straight parts and with treated tape on the ends; the individual strands in the coils and the completed conductors have been insulated with mica tape throughout their entire length. The advantage of the treated tape is that it is flexible and can withstand the slight movements of the coil ends that will occur on short circuits.

An improvement in the micafolium has been made to prevent swelling and wrinkling of the insulation. Research revealed the cause of swelling to be vapor pressure due to the presence of alcohol in the shellac bond of the mica and, to some extent, moisture in the paper used for backing the mica. A new and so-called black bond was therefore developed, and it can be shown that the increase in dielectric loss with temperature for the black bond is almost negligible in comparison with that for the shellac bond.

In preparation for higher operating voltages than 13,800, a special coating for the outside of the coils has been developed to decrease the corona between the sides of the coils and the sides of the slots. If a perfect contact could be made between the coil and the sides of the slots throughout the latter's length, such corona would not exist; if, however, the coil side touches the slot only at points, there is corona from the other points of the coil side. A semiconducting film is therefore required on the surface of the coil in order that all points may be kept at ground potential. Experiments have demonstrated the effectiveness of such a conducting film.

Higher Voltages

Considerable importance is at present attached to the question of using higher voltages for generators of large capacity. Whereas, so far as the manufacture of the machine is concerned, a unit having a capacity of 100,000 kv-a. can be rated at 13,800 volts, nevertheless the cost of circuit breakers, disconnecting switches and busses makes it desirable to build such machines, especially for new generating stations, with terminal voltages as high as 22,000.

Transposed Windings

In order to build machines of extreme core lengths, for large ratings, it became necessary to modify the design of the stator coils. On shorter machines it had been customary to build each coil in one piece, the coil being continuous from the front, without any connection in the rear. Such a coil has the advantage of being turned over in the rear-end connection, i.e., the top conductor of the top coil side in one slot becomes the bottom conductor in the bottom coil side in the return slot. Partial transposition is thereby had and, when additional transposition is provided at the front of the coil, the eddy-current losses remaining will be less than 30 per cent of the copper loss.

If long coils were to be constructed in this manner, they might weigh as much as 350 lb. each, and would be difficult to handle in the insulating process and in the winding of the coils in the core. It is therefore desirable to construct them in halves, and to make connections at both the front and the rear. If it were possible to connect each strand individually at the rear, the structure of the half-coils would be the same as of the full coils so far as eddy current losses are concerned, but unfortunately, in the case of deep coils, such construction is impossible because of insufficient space to make the connections of the many strands. It is therefore necessary to transpose the strands somewhere between the front and rear of the machine, it being the easiest to perform this transposition in the straight, buried part of the coil.

The method used in large machines is a combination of transposition of strands within the slot and transposition outside the slot at the ends of the coils. Every conductor in the coils is split up into groups of several strands in

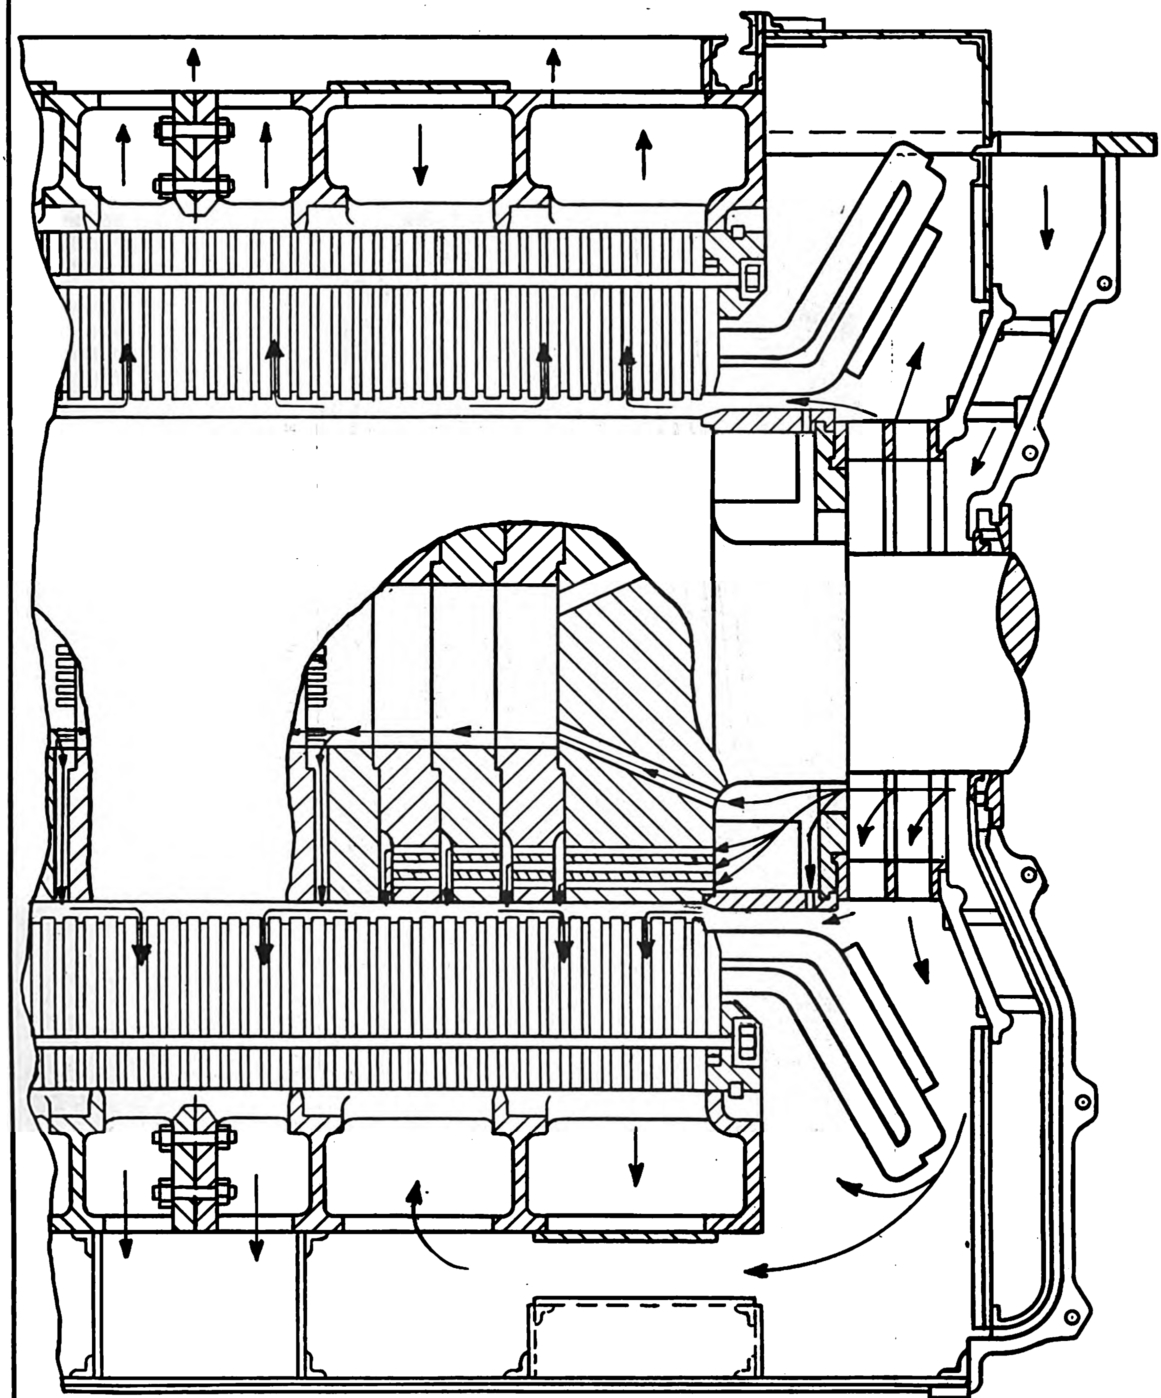

FIG. 33—CROSS-SECTION THROUGH LARGE WESTINGHOUSE GENERATOR SHOWING MODIFIED SYSTEM OF VENTILATION.

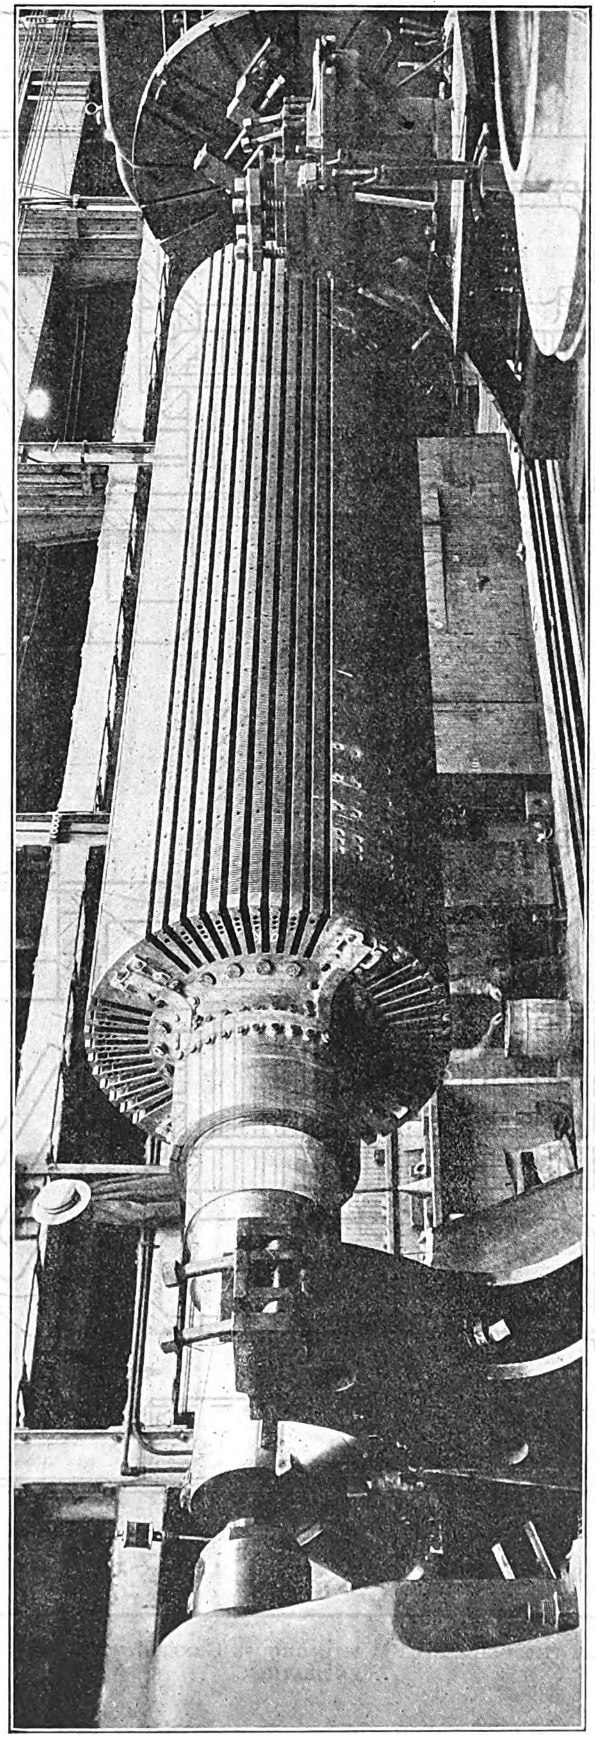

FIG. 34—ROTOR OF 94,000-KV-A. WESTINGHOUSE MACHINE OF THE HOLLOW-PLATE CONSTRUCTION.

depth, and the strands in each group are transposed within the slot to eliminate the eddy currents between the strands in that particular group. The groups are then transposed with respect to each other at the front end of the coil to eliminate the eddy currents between whole groups. One group and the details of one strand are shown in Fig. 38.

Each strand is insulated with mica tape in the same manner as though the coil had no internal transposition. At the points of transposition, half the cross-section of the strand is removed but, because the amount is a small percentage of the total and also because of the high thermal conductivity of copper, the temperature at these points is not materially different from that at other points of the conductor. Tests made with thermo-couples located at different points on the coil have shown no greater temperature variation than would be expected in a conductor of uniform cross-section.

Divided Circuits

Divided circuits have been used to a great extent on large turbo-generators, some of the larger units having as many as three circuits in parallel. The particular windings, however, have always been tied solidly into one bus section and the problem of unbalance between windings has not been encountered.

The use of divided windings has been given considerable study during the past year, particularly with respect to the possibility of connecting the parallel sections of each phase winding to a separate bus in order to reduce the value of normal current that the generator breakers and disconnecting switches are required to carry, and also to reduce the value of short-circuit current which the breakers must interrupt.

An analysis of the situation brings out the following methods of obtaining separate circuits:

Type I—Standard parallel-circuit generators having

A. Windings in two parallel circuits on the same part of the magnetic circuit.

1. When both circuits are equally loaded, the generator is perfectly balanced.
2. When windings are operated at different loads and

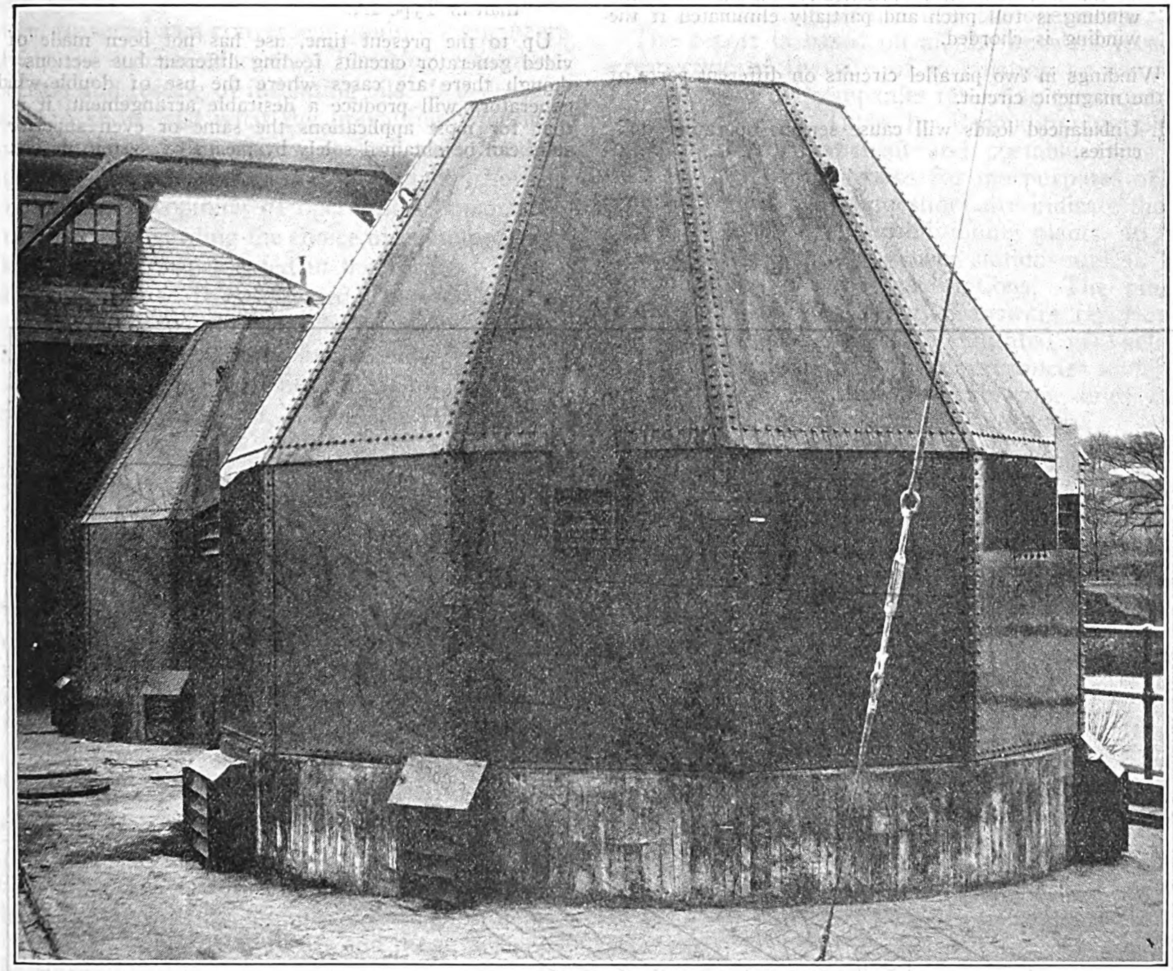

FIG. 37—Installation of Westinghouse Semi-Outdoor Vertical Waterwheel Generators.

different power factors, the generator is perfectly balanced, but consideration must be given to

a. Overloading individual windings.

b. Possibility of obtaining only average voltage regulation of the two windings.

3. When short circuit occurs on one winding only, the other being open-circuited, the current delivered by the one winding will equal approximately that of both windings when short-circuited simultaneously; special end-turn bracing will therefore be required.
4. The reactance between the terminals of the two windings is approximately equal to the sum of the end-leakage reactance of each circuit; the reactance of the slot portion is practically eliminated if the winding is full pitch and partially eliminated if the winding is chorded.

B. Windings in two parallel circuits on different parts of the magnetic circuit.

1. Unbalanced loads will cause serious operating difficulties.
2. When short circuit occurs on one winding, the current will be the same as that per circuit when both windings are short-circuited.
3. Each winding can exert a torque on the common rotor and thus the generators on adjacent busses have considerable capacity for the interchange of synchronizing power.

Type II—Generators having double windings under the same poles but not occupying the same slots.

A. Unbalanced loads may be carried in normal operation.

B. The short-circuit current per circuit is reduced somewhat.

C. There is higher mutual reactance between windings than in Type IA.

Up to the present time, use has not been made of divided generator circuits feeding different bus sections. Although there are cases where the use of double-winding generators will produce a desirable arrangement, it is felt that for most applications the same or even superior results can be obtained solely by means of system design.

STORAGE, HANDLING, TREATMENT, INSPECTION AND TESTING OF INSULATING OILS

This serial report of the Electrical Apparatus Committee shows the trend in practice for the storage and treatment of insulating oils as reported by 57 representative operating companies.

The report includes a summary of the prevailing practice throughout the United States and presents Tables, Data, Appendices and Actual Layouts of outstanding Oil Conditioning Plants.

PURPOSES AND CONCLUSIONS

The report which follows has but one purpose, namely, to serve as a convenient guide for engineers studying the subject of storage, handling, treatment, inspection and testing of insulating oils. It is detailed enough to show just what the prevailing American practice is on various points, as well as to outline minority usage. Actual figures are given showing the consensus of opinion of operating companies.

Conclusions regarding the choice of equipment and methods have been presented in the form of appropriate subcaptions. It is intended that each subcaption shall summarize the prevailing practice outlined in the paragraph or paragraphs immediately following it; as, for example, "Separate Storage Tanks Predominate."

The replies of the various companies reporting indicate that the utilization and reclamation of oils are given exacting attention by the operators.

The report is based on all the answers received, irrespective of the size of installation or company. The names of the companies returning questionnaires will be found in Table I. Reconditioning plants, including both permanent and portable types, are classified into three groups for the purposes of this report. Replies to the questionnaire indicate the existence of 29 central reconditioning plants, 46 local reconditioning plants at power stations and 42 local reconditioning plants at substations. The number of direct positive or negative answers reported by the operating companies are indicated in Table II. It should be noted that the discrepancies in figures not totaling 57 are due to certain companies which were not able to answer all the questions.

PART I

DESIGN OF HANDLING AND TREATING EQUIPMENT

Permanent Facilities Usually at Power Stations

Permanent facilities for the storage and treatment of insulating oils for electrical equipment are provided by more companies at power stations than at central reconditioning plants, and by considerably less than either at local substation reconditioning plants. (Table II, Part I, 1.)

Importance of Installation Determining Factor

At power stations, the decision to install permanent oil handling facilities is based in most cases on the importance of the station. At the substations, however, the amount of oil in use and the importance of the substation are each equally important factors in determining whether such permanent facilities shall be installed. (Table II, Part I, 2.)

Oil Quantities Large

The total quantity of transformer and circuit breaker oil in service varies with the size of the power stations and the substations.

The maximum quantity of transformer oil reported used at power stations was 550,000 gallons and at substations 950,000 gallons. The maximum quantity of circuit breaker oil reported in service at the power stations was 322,000 gallons and at substations was 304,000 gallons. (Table II, Part I, 3.)

Separate Storage Tanks Predominate

The majority of companies provide separate tanks for clean and dirty oil storage at power stations rather than at central reconditioning plants or at substations. (Table II, Part I, 4.)

Separate tanks for transformer and circuit breaker oil respectively are provided at central reconditioning plants and at local reconditioning plants by the majority of companies. Companies each having an installed capacity of 100,000 kv-a. or more provide separate tanks for transformer and circuit breaker oil respectively at all reconditioning plants.

Permanent Tanks Preferred for Clean Oil

Permanent tanks are installed for clean oil storage, in most cases, at power stations and at central reconditioning plants, but only in a limited number of cases at substations. (Table II, Part I, 5.)

Where permanent tanks are not installed for clean oil storage, the majority of companies use drums in preference to portable tanks or tank trucks. The Toledo Edison Company and the Commonwealth Edison Company use portable tanks and tank trucks respectively for handling clean oil at power stations. The Toledo Edison Company also uses portable tanks at its substations; tank trucks are utilized at substations for clean oil storage by the Commonwealth Edison Company and the Puget Sound Power & Light Company respectively. (Table II, Part I, 6.)

Drums Preferred for Dirty Oil

Whereas, permanent tanks for dirty oil storage are installed at power stations by slightly more companies than those which use drums, only a few companies report such tanks at central reconditioning plants and at substations. (Table II, Part I, 7.)

There are, however, several notable exceptions to the indicated preference for drums rather than portable tanks. The Southern Sierras Power Company reports the use of portable tanks, as well as drums, at its central reconditioning plant and at power stations. The Niagara Falls Power Company, in addition to using drums, also uses portable tanks at power station and substation reconditioning plants. The following three companies report the use of portable tanks at their substations: The New York & Queens Electric Light & Power Company, the Niagara Falls Power Company and the Southern Sierras Power Company. The use of a tank truck at substation reconditioning plants is reported by the Puget Sound Power & Light Company. (Table II, Part I, 8.)

Clean Oil Tanks Usually Above Ground

The majority of permanent clean oil storage tanks are located above ground; and except at substations, where they are usually outdoors, opinion seems to be about equally divided as to whether they should be located outdoors or indoors. The Public Service Company of Colorado reports that, due to condensation and water leakage during storage the use of storage tanks placed outdoors and below ground has resulted in a decrease of the dielectric strength. However, Day & Zimmermann, Inc., states that, in its opinion, the location of these tanks depends upon other features of design, and that it has no objection to the installation of tanks below ground. (Table II, Part I, 9.)

No Thermal Insulation for Clean Oil

Permanent clean oil storage tanks are not thermally insulated against atmospheric changes by any reporting company. A few companies report sealing the tanks and using moisture-extracting breathers on clean oil storage tanks at central reconditioning plants. Companies sealing air tight the tanks at central reconditioning plants, when not draining or filling, are the Dallas Power & Light Company, Day & Zimmermann, Inc., and the New York Edison Company. Whenever moisture-extracting breathers are employed, the material used is calcium chloride; such breathers are employed at central reconditioning plants by the Los Angeles Gas & Electric Corporation, the Philadelphia Electric Company, the Puget Sound Power & Light Company and the Idaho Power Company. (Table II, Part I, 10.)

Dirty Oil Tanks Also Above Ground

When provided at central reconditioning plants, separate dirty oil storage tanks are usually located above ground and either outdoors or indoors. The Turner Falls Power & Electric Company has found it advisable to mount its later installations above ground in order to reduce condensation. At power stations the locations for their separate dirty oil storage tanks seem equally divided as to whether they are placed above ground or below ground, and outdoors or indoors. At substations, however, these tanks appear more often to be located outdoors and above ground. Companies having indoor locations at substations are the Cleveland Electric Illuminating Company, the Puget Sound Power & Light Company and the Rochester Gas & Electric Corporation. (Table II, Part I, 11.)

Dirty Oil Tanks Not Air Sealed

Where separate dirty oil storage tanks are used, it seems that very little effort is made to seal them thoroughly or thermally to insulate them against atmospheric changes. The companies using moisture extracting chloride breathers are the Los Angeles Gas & Electric Corporation and the Narragansett Electric Company. The Texas Power & Light Company uses galvanized steel tanks equipped with moisture-extracting breathers at power stations. The only companies sealing their dirty oil storage tanks air tight at substations are Day & Zimmermann, Inc., the Philadelphia Electric Company and the Turner Falls Power & Electric Company. (Table II, Part I, 12.)

Tank Capacities Evenly Divided

From a study of the capacity of clean oil storage tanks, it is felt that substations have on the average more local tank capacity for transformer oils than either central reconditioning plants or power stations. As far as circuit breaker clean oil tanks are concerned, power stations have the greatest capacity. (Table II, Part I, 13.)

In regard to dirty oil storage tanks for transformer oil, it has been found that the larger sizes are at power stations. For storing dirty circuit breaker oil, the tanks at both power stations and substations have essentially the same average capacity. Apparently very little dirty circuit breaker oil is stored at central reconditioning plants, for the general practice is to treat and return the oil to service as fast as it arrives, thus avoiding the necessity for large storage tanks. (Table II, Part I, 14.)

Oil Capacity Provided for Largest Unit

Most of the companies reporting provide both clean and dirty oil tanks of sufficient capacity to hold the oil from the largest unit. However, whereas the Shawinigan Water Power Company provides clean oil tanks of sufficient capacity to take care of the oil for its largest unit, it does not provide sufficient dirty oil tank capacity. (Table II, Part I, 15.)

Independent Oil Lines Provided

Independent oil lines are provided for clean and dirty oil respectively in all three types of reconditioning plants, and the same decision appears to hold true in the operation of oil lines for transformer and circuit breaker oil respectively. Table II, Part I, 16.)

Permanent Piping Usually Above Ground

In the majority of cases reports indicate that permanent oil piping is located above ground except at substations, where it is buried unprotected in the ground. At central reconditioning plants some of the companies burying their pipe lines in concrete or protective envelopes are the Brooklyn Edison Company, the Bronx Gas & Electric Company and the Canadian Niagara Power Company. Some of the companies which, at substations, provide accessible trenches for their piping, considering flexibility and continuity of operation an item worthy of consideration, are the Detroit Edison Company, the Niagara Falls Power Company, the New York & Queens Electric Light & Power Company and the Rochester Gas & Electric Corporation. (Table II, Part I, 17.)

Wrought Iron and Steel Piping Used

Regarding the material used for piping, it is found that wrought iron has been used by the majority of companies for all three locations. At power stations some companies using uncoated steel are the Philadelphia Electric Company, the Public Service Company of Colorado and the Shawinigan Water Power Company. Wrought iron and galvanized steel are specified equally for substation use. Four companies report the use of uncoated steel pipe: namely, the Philadelphia Electric Company, the Public Service Company of Colorado, Duquesne Light Company and Day & Zimmermann, Inc. (Table II, Part I, 18.)

Piping Connected Permanently

The great majority of companies report that their piping is permanently connected to the electrical equipment. At the same time, however, provision has been made by most of the companies to connect the electrical equipment to the oil piping by means of flexible metallic hose. Further flexibility is secured by providing means for cutting in portable oil heating apparatus in the oil lines of the electrical equipment if, upon occasion, the permanent heating units should develop trouble. (Table II, Part I, 19-20-21.)

Non-portable Types of Equipment Used

The use of different types of non-portable equipment at the central reconditioning plants appears to be equally divided between centrifugal and filter press equipment. A few companies are using both types of treating equipment in order to secure complete reconditioning when treating very dirty oil. The Duquesne Light Company is the only company reporting the installation of chemical treating equipment. The Rochester Gas & Electric Corporation uses lye when treating badly burned oil, showing discoloration or sludging; it uses one pound of lye to approximately three barrels of oil. Non-portable equipment is used at both power stations and substations, with the filter press type predominating. (Table II, Part I, 22-23.)

The prevailing rated capacity of non-portable centrifugal apparatus for use in central and local plants is 600 gallons per hour at a temperature of 50 deg. cent.; the prevailing rated capacity of filter press equipment for use in central and local plants, 1000

TABLE II

SUMMARY OF INSULATING OIL PRACTICES

Part One—Design of Oil Handling and Treating Equipment	At Your Central Reconditioning Plant		At Your Local Reconditioning Plants			
			At Power Stations		At Substations	
	Yes	No	Yes	No	Yes	No
1. Do you provide permanent facilities for:						
a. The storage of oils for electrical equipment	29	10	30	19	22	25
b. The treatment of these oils	28	9	35	14	22	24
2. Is the decision to install permanent oil handling facilities at individual stations based on:						
a. Importance of station	....	....	36	3	25	6
b. Amount of oil in use at the typical station you are describing { transformer oil / oil circuit breaker oil }	....	....	32	1	27	2
c. Distance or inaccessibility of station from central oil treating facilities	....	....	21	9	16	9
3. Referring to the particular stations at which the individual plants you are reporting on are located:			(Min.)	(Max.)	(Min.)	(Max.)
a. What is the total quantity of transformer oil in service (state in gallons)	....	....	7,000	550,000	2,700	950,000
b. What is the total quantity of oil circuit breaker oil in service (state in gallons)	....	....	1,000	322,000	2,500	304,000
4. Are separate tanks provided for:						
a. Clean and dirty oil storage	22	14	31	14	17	20
b. Transformer and oil circuit breaker oil	19	16	22	19	16	19
5. Are permanent tanks installed for clean oil storage	24	13	29	18	18	21
6. If not, what are used in their stead (drums, portable tanks, tank trucks, etc.) Drums	16	1	18	3	19	3
Port. tanks	0	2	1	2	3	2
Tank trucks	0	2	1	1	2	2
7. Are permanent tanks installed for dirty oil storage	16	19	26	18	15	24
8. If not, what are used in their stead (drums, portable tanks, tank trucks, etc.) Drums	20	3	20	1	22	0
Port. tanks.	1	3	2	1	4	1
Tank trucks	0	4	0	2	1	2
9. Are clean oil storage tanks located:						
a. Above ground	24	5	22	13	17	9
b. Below ground	7	16	14	17	10	12
c. Outdoors	16	11	21	12	22	4
d. Indoors	17	9	20	17	9	14
10. Are they:						
a. Thermally insulated against atmospheric changes	0	32	0	41	0	31
b. Sealed air tight when not draining or filling	4	27	9	32	7	23
c. Equipped with moisture extracting breathers	5	26	9	32	6	24
11. If separate dirty oil storage tanks are provided are they located:						
a. Above ground	17	1	15	5	9	2
b. Below ground	3	8	13	8	7	3
c. Outdoors	9	4	14	12	10	0
d. Indoors	11	5	15	11	3	8
12. Are they:						
a. Thermally insulated against atmospheric changes	0	20	0	28	0	15
b. Sealed air tight when not draining or filling	5	15	8	21	3	0
c. Equipped with moisture extracting breathers	1	18	4	25	2	14
13. What is the capacity of clean oil storage tanks which are used for:	(Min.)	(Max.)	(Min.)	(Max.)	(Min.)	(Max.)
a. Transformer oil (state in gallons)	1,000	75,000	1,000	30,000	1,250	60,000
b. Oil circuit breaker oil (state in gallons)	600	45,000	4,400	30,000	1,000	36,000
14. What is the capacity of dirty oil storage tanks which are used for:						
a. Transformer oil (state in gallons)	600	5,000	1,000	39,000	1,200	10,000
b. Oil circuit breaker oil (state in gallons)	1,200	26,000	1,250	23,500	1,200	10,000
15. Are clean and dirty oil tanks each of sufficient capacity to hold the oil from the largest piece of equipment in the station	....	....	37	1	28	1
16. Are independent oil lines provided for:						
a. Clean and dirty oil	15	10	26	15	20	12
b. Transformer and oil circuit breaker oil	7	11	20	16	13	11
17. Is permanent oil piping run:						
a. Above ground	16	6	20	15	9	14
b. Below ground in a concrete or other protective envelope	3	11	12	14	6	12
c. Buried, unprotected	6	5	14	15	18	7
d. Below ground in an accessible trench	9	2	17	14	9	13
18. Is the following material used for permanent piping:						
a. Wrought iron	15	2	21	12	13	11
b. Uncoated steel	6	7	5	16	4	13
c. Galvanized steel	7	9	12	12	12	11
d. Other material (state material)	1	10	1	17	2	15
e. Are joints welded	1	19	1	30	1	24

TABLE II—(*Continued*)

SUMMARY OF INSULATING OIL PRACTICES

Part One—Design of Oil Handling and Treating Equipment	At Your Central Reconditioning Plant		At Your Local Reconditioning Plants			
			At Power Stations		At Substations	
	Yes	No	Yes	No	Yes	No

TABLE II—(*Continued*)

SUMMARY OF INSULATING OIL PRACTICES

Part Two—Operation and Maintenance of Oil Handling and Treating Equipment	At Your Central Reconditioning Plant		At Your Local Reconditioning Plants			
			At Power Stations		At Substations	
	Yes	No	Yes	No	Yes	No
23. Do you successfully remove carbon from circuit breaker oil by:						
a. Centrifuge	6	18	10	14	6	13
b. Filter press	19	8	24	3	29	5
c. Combination of centrifuge and filter press	16	6	14	4	1	7
d. Chemical treatment	2	7	0	12	0	8
e. Other processes (describe method)	....	....	See	Text		
24. What is the total volume of oil reconditioned per year for:						
a. Transformers (state in gallons)	....	....	See	Text		
b. Circuit breakers (state in gallons)						
25. Insert values for average pass of oil through various pieces of equipment	....	....	See	Table 3		
26. Describe in detail any of the following operating difficulties which you experience in any now commercially available oil purification processes which you use:						
a. Design			See	Text		
b. Mechanical defects						
c. Electrical defects						
d. Inadequate capacity due to failure to meet ratings						
e. Inadequate quality of oil						
f. Excessive operating cost						
g. Lack of portability						
h. Difficulty in training operators to obtain satisfactory and consistent results						

Part Three—Use and Inspection of Insulating Oils	Yes	No
1. Do you purchase the following insulating oils on specification:		
a. Transformer oil	11	47
b. Circuit breaker oil	8	46
2. If answer to 1 is "yes," please submit copies of the complete specifications used	See Appendic	es 3 and 4
3. Do you purchase your insulating oils from the following:		
a. Electrical apparatus manufacturer	56	0
b. Oil refiner	11	30
c. Oil jobber	1	38
4. Do you inspect and test the following new oils as received:		
a. Transformer oil	46	11
b. Circuit breaker oil	43	12
5. State the limits of physical, chemical, and electrical qualities which the oil must meet before it is accepted by your company	See Tab	le 4
6. Do you find oil from new shipments to obtain:		
a. Water	32	24
b. Sediment or "dirt"	20	32
c. Metallics	12	37
7. Do you transfer your oil shipments to storage tanks when received	27	26
8. Do you dehydrate or blotter press new oil shipments:		
a. On receipt, before storing	21	30
b. After storing and prior to using	48	6
9. State the ratio in percent of the new oil maintained in storage to the total oil in service on the system:	(Min.)	(Max.)
a. Transformer oil (all applications) %	1	10
b. Circuit breaker oil (for indoor types) %	1	50
c. Circuit breaker oil (for outdoor types) %	1	15
10. Do you find any change in the quality of new oil after it is installed in apparatus but before apparatus is energized	15	38
11. If answer to 10 is "yes," describe briefly the changes experienced and methods of overcoming same	See	Text
12. Do you have a scheduled inspection period for oil in service	52	5
13. State length of time between inspections for oil in:		
a. Indoor transformers	See	Text
b. Outdoor transformers		
c. Indoor circuit breakers		
d. Outdoor circuit breakers		

TABLE II—(*Continued*)

SUMMARY OF INSULATING OIL PRACTICES

Part Three—Use and Inspection of Insulating Oils	Yes	No
14. Which of the following methods do you use for determining the condition of oils in service:		
a. Visual inspection for sediment	37	6
b. Dielectric strength	55	1
c. Free water	20	12
d. Carbon	18	8
e. Physical tests	4	25
f. Chemical tests	6	25
15. If answer to 14-e or 14-f is "yes," describe briefly the nature of tests	See	Text
16. Have you established limiting values in the properties of oil as determined from periodic test which dictate that oil in apparatus should be changed	42	10
17. If answer to 16 is "yes," describe briefly the oil characteristics and limiting values used:		
a. Electrical	See	Text
b. Physical		
c. Chemical		
18. Have you experienced any difficulty in equipment operation due to mixture of serviced transformer and circuit breaker oil in the apparatus	1	51
19. If answer to 18 is "yes," describe the difficulty and your method of overcoming	See	Text
20. Would your company be able to effect economies in oil utilization if the apparatus manufacturers would reduce the required number of oils to:		
a. One for outdoor and indoor transformers	28	14
b. One for outdoor and indoor circuit breakers	31	21
21. If answer to question 20 is "yes," by what percent would you be able to reduce your storage stock of oils:	(Min.)	(Max.)
a. Transformer oil.......%.	10	50
b. Circuit breaker oil.......%.	10	50
22. If you recondition your oils, what are the quality limits required or found before oil is reused:	(Min.)	(Max.)
a. Dielectric strength (kv. 1/10 in. gap).......kv.	22.0	26.0
23. Have you experienced any inability to maintain adequate quality of reconditioned service oil in the apparatus after it has been reconditioned	7	38
24. Do you make an inspection of the oil in oil circuit breakers:		
a. After every automatic operation	10	11
b. If answer to 24-a is "yes," what is the elapsed time between operation and inspection	See	Text
c. If answer to 24-a is "no," how many automatic operations take place before inspection of oil	See	Text
25. Do you use any sampling connections on transformers other than that supplied by the manufacturer	8	46
26. If answer to 25 is "yes," describe briefly	See	Text
27. Do you use any sampling connections on circuit breakers other than that supplied by the manufacturer	12	43
28. If answer to 27 is "yes," describe briefly	See	Text
29. Are sampling connections desirable at other points on equipment than normally supplied by the manufacturer in order to permit taking a more representative sample	10	42
30. If answer to 29 is "yes," describe the locations in transformers and breakers which you consider would give a more representative sample of oil	See	Text

gallons per hour at a temperature of 50 deg. cent. (Table II, Part I, 24.)

Electric Heaters Predominate

Facilities for heating oils during treating processes include electric heaters in the majority of cases. Very few companies use steam or other facilities for heating. The Detroit Edison Company has installed 5 kw. 220 volt heaters under its circuit breaker tanks, for use during severe weather. The Dayton Power & Light Company employs two immersion heaters rated at 2 kw. each. The Duquesne Light Company reports the installation of steam heating units in their reconditioning plant in order to prevent oxidation of aerated oil produced by the use of electrical heating units which have no adequate temperature control. (Table II, Part I, 25-26.)

Filter Press Choice in Portable Equipment

For portable equipment at central and local reconditioning plants the greatest usage seems to lie in filter press apparatus. The Dayton Power & Light Company and the Texas Power & Light Company are each using a combination unit consisting of a centrifuge and a filter press mounted on one machine. (Table II, Part I, 27-28.)

Equipment Rated Capacities Vary Widely

For portable apparatus at power stations the rated capacity of centrifugal equipment varies from 100 to 800 gallons per hour at a temperature average of 50 deg. cent., and filter press equipment ranges in capacity from 200 to 1800 gallons per hour at a temperature average of 50 deg. cent., depending upon the size of the company. The rated capacity of the centrifugal equipment most frequently used is 400 gallons per hour; for the filter press equipment most frequently used the rated capacity is 800 gallons per hour.

TABLE III

MINIMUM AND MAXIMUM VALUES OBTAINED IN THE OPERATION OF RECONDITIONING EQUIPMENT

	Centrifuge		Filter Press		Centr. and Filter Press	
	Non-Portable	Portable	Non-Portable	Portable	Non-Portable	Portable
a. Actual output, gals. per hr., min.-max.	150 to 1500	60 to 800	150 to 2000	150 to 1800	300 to 1000	100 to 500
b. Actual oil temperature °C. during operation, min.-max.	35 to 70	35 to 90	25 to 72	20 to 75	70 to 100	50 to 70

PART II

OPERATION AND MAINTENANCE OF HANDLING AND TREATING EQUIPMENT

Interior Surfaces Do Not Rust

Only a comparatively few of the fifty-seven reporting companies have found it necessary to apply paint or varnish in order to prevent rusting on interior surfaces of transformers or oil storage tanks and containers. The materials used by these companies include shellac, red metal paint, lacquer, varnish and bakelite varnish. The Edison Electric Illuminating Company of Boston uses bakelite varnish and a cork lining on covers, as well as an external coating of paint and ground cork, in order to prevent internal condensation. The Idaho Power Company applies to the transformer covers, after a thorough cleansing, three coats of shellac. (Table II, Part II, 1.)

High Dielectric Strength Maintained

Many companies have facilities for maintaining during storage an adequate dielectric strength for more than six months, on an average, at their central reconditioning plants and for more than twelve months, on an average, at their power stations. The methods of accomplishing this result are varied. The Commonwealth Edison Company keeps the clean oil storage tanks entirely filled up in order to avoid entrapped air spaces and, when necessary, the oil is centrifuged. The Kansas City Power & Light Company stores the drums with the bungholes pointed down, thereby preventing the collection of water in empty drums. The Rochester Gas & Electric Corporation keeps the temperature of the room containing oil tanks at 15 deg. fahr. above the outside air temperature. The majority of the other companies maintain the dielectric strength by reconditioning the oil more frequently than condensation can occur in any appreciable quantity; others use small tanks and frequently change their oil. Since the average practice is to filter into and out of storage, no appreciable trouble is encountered in maintaining an adequate dielectric strength. (Table II, Part II, 2-3-4.)

Tanks Washed with Clean Oil

No apparent trouble in maintaining the cleanness of permanent oil storage tanks has been found, due to the methods employed in keeping this equipment clean. Almost all the companies report a periodic cleaning, ranging in time from four to six months, by flushing with clean oil and wiping when empty. The Southern California Edison Company paints the outside of its tanks with red lead and finishing coats, after sand blasting. The New York Edison Company keeps clean oil tanks in a dry, heated building. The Brooklyn Edison Company cleans and shellacs tanks yearly at the central and local reconditioning plants. (Table II, Part II, 5-6.)

The prevailing practice in the cleaning of portable tanks and drums is also to wash with clean oil. The only companies reporting washing by means of steam at central reconditioning plants are Day & Zimmermann, Inc., the Puget Sound Power & Light Company and the Rochester Gas & Electric Corporation. No use of water and alkali is reported for cleaning portable equipment. Neither has it been in many instances necessary to dry the containers by some means of heating or blowing, although the use of ovens at central plants for drying purposes is reported by the Puget Sound Power & Light Company and the Idaho Power Company, which operate these ovens at temperatures of 75 and 85 deg. cent. respectively. The Grays Harbor Railway & Light Company dries drums by placing them over the smoke ducts in the boiler room. The Southern California Edison Company is the only organization reporting the use of blowers for drying purposes after cleaning portable tanks and drums. (Table II, Part II, 7.)

Containers Rigidly Inspected

Reports indicate that inspection for rust or sediment in fixed containers is regularly conducted by the majority of companies, the method of inspection usually depending upon visual examination of tank interiors. At the Milwaukee Electric Railway & Light Company and the Texas Power & Light Company, it is customary for an operator to enter the tank being inspected. Another method of inspection includes sampling the oil for rust, and is employed by the Edison Electric Illuminating Company of Boston. (Table II, Part II, 8-9.)

A majority of the reporting companies inspect portable containers for rust or sediment by the visual method. The Puget Sound Power & Light Company uses a light lowered through the bungholes in order better to inspect the inside surface. (Table II, Part II, 10-11.)

Oil Usually Transported in Drums

In transporting oil to and from permanent reconditioning plants or central storage, drums are used by the majority of companies. At the central reconditioning plants, the practice is to use tank trucks, tank cars or portable tanks; the Commonwealth Edison Company, The Puget Sound Power & Light Company and the Southern California Edison Company using tank trucks whenever drums are not employed. At the power station and substation reconditioning plants, the practice is to use pipe lines, tank cars or portable tanks whenever drums are not used. It is to be noted that, at stations and substations, pipe lines are used for the local transportation of oil in more cases than any other instrumentality with the exceptions of drums. (Table II, Part II, 12.)

Pipe Joint Leakage Greatest Maintenance Trouble

Considerable trouble in the maintenance of oil piping is due to joint leakage, valve seat leakage and valve packing leakage, the greatest difficulty being experienced with the former. The remedy for joint leakage which has proved most valuable to the Public Service Company of Northern Illinois and the Texas Power & Light Company in the maintenance of oil pipe lines at reconditioning plants is first to cover the threads with white lead and oil, and then to cover them with bakelite varnish and a General Electric compound known as No. 880. Recommended remedies for leakage in valve seats and packing for the most part comprise renewing the seat or replacing the valve. (Table II, Part II, 13.)

No Difficulty Experienced from Congealing

No difficulty has been experienced by any company due to the congealing of oil in buried lines; satisfactory preventive measures having been obtained by burying the pipe to a depth of from two to three feet, by pre-heating the oil and by running steam lines in the same trench with the oil lines—the latter method being used by Day & Zimmermann, Inc. Thermal insulation is not employed by any reporting company to prevent the congealing of oils. The Public Service Electric & Gas Company (New Jersey), in order to prevent congealing in buried pipe lines and otherwise, requires that oil furnished for apparatus shall not congeal above a temperature of minus 20 deg. C. (Table II, Part II, 14-15.)

Pipe Corrosion Negligible

Corrosion of pipe lines buried in the soil is experienced more at substations than at either central reconditioning plants or local power station reconditioning plants, but the number of replies indicating any corrosion at all is relatively few. Day & Zimmermann, Inc., reports that the corrosion of its buried oil lines is due to the cinder fill used. Electrolysis and water drainage do not seem to be appreciable factors in causing the corrosion of the pipe lines of any reporting company. (Table II, Part II, 16-17.)

Several methods of combating corrosion of pipes are being used. The Pacific Gas & Electric Company cleans its pipes and coats them with tar. The Southern Sierras Power Company coats its pipes with pitch or with burlap strips dipped in hot asphalt. The Utah Power & Light Company reports that corrosion of buried oil lines is prevented by protecting the outer surface of the pipe with a coating of red lead. (Table II, Part II, 18.)

No Clean Oil Remains in Unused Lines

At their central reconditioning plants, as well as at their power stations and at their substations, the majority of companies do not permit clean oil to remain in pipe lines not in actual use. (Table II. Part II, 19.)

Filter Presses Preferred

When dehydrating transformer oil at central and local reconditioning plants, more companies use the filter press method than any other, although several companies use a combination centrifuge and filter press at all reconditioning plants. The only additional method employed in dehydrating transformer oil is the use of a filter of Fuller's earth, reported by The Shawinigan Water Power Company. Test runs with Fuller's earth have also been conducted by the Commonwealth Edison Company, which reports that the oil was successfully dehydrated. (Table II, Part II, 20.)

More circuit breaker oil is successfully dehydrated by filter press than by centrifuge or by a combination of centrifuge and filter press. (Table II, Part II, 21.)

The filter press is also accepted as the favorite apparatus for the removal of sediment and sludge from transformer and breaker oil, although the centrifuge and the combination of the two are also used and even the filter of Fuller's earth has some advocates. The San Diego Consolidated Gas & Electric Company reports the use of the following unusual formula for the removal of carbon: add one pound of gold dust dissolved in two gallons of water to fifty gallons of oil, heat to 200 deg. fahr. for one-half hour, then agitate with steam jet and run through centrifuge with water seal. The Rochester Gas & Electric Corporation reports that transformer and breaker oils are treated with lye when the presence of acid is noted; for burned oil showing discoloration, one pound of lye is used to three barrels of oil. The Cleveland Electric Illuminating Company reports that it is unable to remove all traces of carbon from heavily carbonized breaker oil but that the dielectric test, after one run through the centrifuge at 200 gallons per hour, is better than 25 kv. Operating instructions on the subject, issued by Charles H. Tenney & Company, are given in Appendix I. (Table II, Part II, 22-23.)

An engineering letter of the Electric Bond & Share Company, comparing the filter press and the centrifuge, is given in Appendix II.

Total Reconditioned Oil Volume Large

Some interesting figures have been obtained in regard to the total volume of transformer oil reconditioned each year by various operating companies. The New York Edison Company heads the list of companies reporting, with 400,000 gallons per year at its central reconditioning plant. The Alabama Power Company reports the greatest quantity handled by local reconditioning plants at power stations and at substations, the figures being 306,000 and 432,000 gallons per year respectively. (Table II, Part II, 24.)

Figures on the total volume of circuit breaker oil reconditioned per year are also significant. The Philadelphia Electric Company handled the largest quantity of any central reconditioning plant, viz., 80,892 gallons. The maximum quantity of oil reconditioned by any one company at power stations is 650,000 gallons, the figure submitted by the Duquesne Light Company. The largest quantity reported by any company under any method of reconditioning is the 1,100,000 gallons at the substation reconditioning plants of the Southern California Edison Company.

Experience with Two Types Varies

Comparison between the filter press and the centrifuge, in operating experience for one pass of oil, is given in Table III. It should be noted that two passes through the oil treating equipment are usually necessary in order to secure the return of a high dielectric strength. The number of hours of continuous operation between changing of blotters or cleaning of equipment depends entirely upon the original condition of the oil. The variation in filter press costs per thousand gallons of oil is so wide that it is omitted from this report. This variation can best be understood by an examination of the methods employed in treating very dirty oil; the companies showing low blotter costs make a practice of running their oil first through the centrifugal apparatus and then through the filter press, and are therefore able to use their blotters over again when handling fairly clean oil. (Table II, Part II, 25.)

Many Operating Difficulties Experienced

Many difficulties have been encountered in the operation and maintenance of handling and treating equipment. With regard to design defects, it has been reported that the time required to start and to stop the centrifuge is too great, that a blotter press driven by a repulsion motor constitutes a fire hazard as the result of motor sparking, that oil accumulation on the commutator contributes to dust collection and the motor should therefore be entirely inclosed, that a safety switch should be provided at the motor, and that thermostatic control of blotter press heaters would make operation simpler and safer.

With regard to mechanical defects, it has been reported that a by-pass relief valve should be placed on the centrifuge, that difficulty is experienced in cleaning centrifuges of certain types, that blotter press bearings require too frequent renewal, that difficulties have been experienced in renovating oil with the filter press in cold weather although the application of heat to the oil will probably overcome them, and that blotters should be shipped from the factory in sealed packages in order to eliminate the absorption of moisture during transportation.

With regard to electrical defects, it has been reported that certain electrical heaters are too small and not sufficiently rugged, that trouble has arisen from the burning out of heating units, that it has been necessary to replace centrifuge switches having insufficient capacity, that centrifuge heaters do not have sufficient capacity, that the electrical connections of heaters under blotters often become damaged because of insufficient flexibility and that heaters for portable presses should be weatherproof.

Numerous companies are experiencing difficulties in the consideration of ratings, it being stated that the rating of equipment depends entirely on the dirtiness of the oil, and that no comparison should be made between the actual rating and the rating given by the manufacturer; centrifugal equipment particularly is reported to be considerably overrated. It is quite obvious that the quality of oil obtained from centrifuge or filter press depends entirely on the dirtiness of the oil; it has been reported that it is sometimes necessary to pass oil once through a press after two or three passes through a centrifuge in order to dehydrate it and that, in a few cases, sludge could not be removed with a centrifuge.

In discussing the question of portability, the operating companies seem to feel that portable presses and heaters should be lighter and should be weatherproof, should be arranged for shipment without crating and should be provided with larger wheels, designed for running on cinders and loose dirt, and that containers for storing dry blotters should be added. The general opinion seems to be that the centrifuge requires a more skilled operator than the filter press, particularly on centrifuges necessitating the changing of dams to accomplish dehydrating economically, in which case operators find it difficult to select the proper size of dam. Operators also report difficulty in consistently maintaining the required oil temperature to the centrifuge, and in passing the hot oil to the cold breaker tanks without condensation and consequent decrease of dielectric strength. (Table II, Part II, 26.)

Total Costs Greatly Varied

The reconditioning costs per thousand gallons of oil submitted by a comparatively few companies were so divergent and contained so many unknown quantities that it is impossible to draw conclusions from them and they are therefore omitted from the report.

PART III

USE AND INSPECTION OF INSULATING OILS

Few Specifications in Existence

In the present state of oil treating and handling, very few companies purchase their insulating oils on detailed specifications. It seems rather to be the common practice for the operating companies to use the oils suggested or recommended by the equipment manufacturers for transformers and oil circuit breakers respectively. However, a growing tendency is noted toward the use of individual operating companies of their own detailed purchase specifications covering insulating oils. (Table II, Part III, 1.)

Such specifications, in use by the Commonwealth Edison Company and the New York & Queens Electric Light and Power Company, are given in Appendices III and IV respectively. (Table II, Part III, 2.)

Purchases Made from Equipment Manufacturers

The great majority of companies still purchase their insulating oils from the respective equipment manufacturers. However, a number of companies on the Pacific Coast buy directly from oil refiners, as do several of the largest utility companies scattered about the country. (Table II, Part III, 3.)

Inspection and Tests Made of New Oils

Inspection and tests of new oils are reported by the vast majority of companies, an indication that good care is taken to obtain proper oil. Average values for all the specified items are shown in the accompanying table of limits, designated Table IV. The tendency towards uniformity in the two classes of figures can best be explained by the fact that a large number of companies are using one oil for both transformers and circuit breakers. (Table II, Part III, 4-5.)

New Oil Received in Unserviceable Condition

Most companies report finding water, sediment and metallics in new oil shipments. The number of companies frequently finding water in their new oil is about twice the number finding sediment or dirt and about three times the number finding metallics. Because of these conditions, a considerable number of reporting companies make a practice of passing new oil through centrifuge or filter press before transferring it to storage tanks. After storage, on the majority of systems, the oil is similarly treated prior to being used when it does not meet the required dielectric test. (Table II, Part III, 6-7-8.)

TABLE IV

MINIMUM AND MAXIMUM LIMITING QUALITIES WHICH OIL MUST MEET BEFORE ACCEPTANCE

Tests	Transformer Oil, All Applications	Circuit Breaker Oil		Number of Companies Reporting
		Indoor	Outdoor	
a. Specific gravity at 15/15 °C. (min.-max.)	0.82 to 0.90	0.82 to 0.90	0.82 to 0.90	3
b. Flash test (°C.) (min.-max.)	130 to 150	130 to 188	130 to 180	7
c. Fire test (°C.) (min.-max.)	140 to 165	149 to 210	149 to 210	5
d. Pour test (°C.) (min.-max.)	Zero to minus 40	Minus 4 to minus 40	Minus 4 to minus 40	7
e. Viscosity Saybolt at 37.8 °C.—sec. (min.-max.)	55 to 65	55 to 128	55 to 121	7
f. Neutralization number (milligrams, KOH)		Must Be	Neutral	4
g. Sulphur corrosion	None	None	None	4
h. Dielectric strength—kv. across 0.1 inch gap (min.-max.)	20 to 31	20 to 31	20 to 30	26
i. Sediment (% by volume)	None	None	None	3
j. Sediment (% by weight)	None	None	None	2

Stored Oil Averages Five Per Cent

The ratio of new oil maintained in storage to the total oil in service on the system averages approximately 5 per cent for all classes of oil. For transformer oil, this ratio varies between one per cent and 10 per cent, and for indoor circuit breaker oil, the ratio varies between one per cent and 50 per cent. One western utility company reports as high as 50 per cent and a large middle western company reports a ratio of 30 per cent. For outdoor circuit breaker oil, the largest ratio reported was 15 per cent. (Table II, Part III, 9.)

Quality May Change in Deënergized Apparatus

Although the majority of reporting companies have experienced no difficulty with changes in the quality of oil remaining in apparatus which is not energized for a considerable period, companies reporting that such oil absorbs moisture are in sufficient number to indicate that a very real difficulty exists in this respect. Only two methods have been reported as being employed to eliminate this moisture and none to prevent absorption; the elimination methods are refiltering of the oil and drying out of the apparatus by means of circulating currents. (Table II, Part III, 10-11.)

Semi-Annual Inspection Periods

Approximately fifty companies report scheduled inspections of oil in service. The average length of time between inspection is seven months for indoor transformers, six months for outdoor transformers, nine months for indoor circuit breakers and six months for outdoor circuit breakers. Charles H. Tenney & Company has a scheduled inspection period for oil in service of once every four months for transformers and oil switches operating at 13,200 volts or higher; and of once every year for line transformers having a capacity of 25 kv-a. or more, operating at less than 13,200 volts, all subway transformers, and all station oil breakers except breakers of such types as are placed in special classes and therefore have their oil replaced by tested oil at each overhauling. (Table II, Part III, 12-13.)

The following test methods, in the order of their stated preference, are used for determining the condition of oils in service: dielectric strength, visual inspection, free water, carbon, chemical tests and physical tests. Both the Philadelphia Electric Company and the Louisville Gas & Electric Company make complete chemical analyses and dielectric tests on transformer oils every three months, and on circuit breaker oils at three months' intervals or after heavy duty performance, in accordance with the test program being conducted by the Insulating Oil Subcommittee of the N. E. L. A. Electrical Apparatus Committee. (Table II, Part III, 14-15.)

Tests Determine When Oil Should Be Changed

The majority of companies have established limiting values in the properties of oil as determined by periodic tests, which values dictate that oil in apparatus should be changed. The electrical limiting values range from 15,000 volts as a minimum requirement up to 25,000 volts as a maximum. Some of the determining physical characteristics are found to be had when a sample shows considerable carbon, when there is heavy sludge, free water and free carbon present, and when excessive sludging is indicated by overheating of the transformer. (Table II, Part III, 16-17.)

Serviced Oils Freely Mixed

No difficulty has been experienced from the use of a mixture of serviced transformer and circuit breaker oils by the vast majority of the reporting companies. It would seem unlikely that trouble should occur, provided that care is taken in obtaining good oil and in mixing only oils having similar characteristics. Operating instructions to the contrary, issued by The Philadelphia Electric Company, are given in Appendix V. (Table II, Part III, 18-19.)

Standardization Would Effect Vast Economies

Approximately one-fifth of the reporting companies are using only one oil for outdoor and indoor circuit breakers and approximately two-fifths are using one oil for both outdoor and indoor transformers. These companies report that their storage stocks of oil would be reduced from 10 to 50 per cent by the use of one oil for outdoor and indoor transformers and for outdoor and indoor circuit breakers. (Table II, Part III, 20-21.)

Reconditioned Oil Has Good Characteristics

When reconditioning oils, most of the companies strive to bring them back to the original condition. The figures given by the majority of companies for the reconditioned dielectric strength of transformer and circuit breaker oil do not materially vary from the respective limiting values used at the time of the original purchase. Furthermore, most companies require that the reconditioned oil shall be free from sediment or sludge, and free from water. When these conditions are complied with, very few companies experience any trouble in maintaining the quality of oil in service. (Table II, Part III, 22-23.)

Circuit Breaker Inspections at Short Interval

Only a small percentage of the companies report making inspection of oil in circuit breakers after every automatic operation of severe intensity, the number being, however, half of the twenty-one companies sending in information on the subject: these same companies report inspection of oil following each operation of their high voltage breakers. It should be noted that nearly all inspections are made within an average elapsed time of six hours after the breaker operation. Several large companies report their inspections conducted within twenty-four hours of elapsed time. Many others inspect after every severe operation. As to the number of automatic operations taking place before the inspecting of oil, the average is found to be six times. However, the actual number of times ranges from one to twenty, depending entirely upon the severity of operation and such signs of distress as the throwing of oil. (Table II, Part III, 24.)

Present Sampling Methods Suitable

Very little tendency to use any transformer sampling connections other than those supplied by the manufacturers is noted. Reports would indicate that the operating companies are apparently satisfied with the present installed sampling devices. However, a few companies feel it necessary to add refinements. The Edison Electric Illuminating Company of Boston has installed sampling cocks mounted outside of the main draw-off cock. The Southern Sierras Power Company has installed sampling pipes and petcocks in order to make it more convenient to secure a sample of oil without using the large valves. Day & Zimmermann, Inc., and the Public Service Electric & Gas Company (New Jersey) have all their transformers in excess of 750 kv-a. equipped with sampling valves independent of the drain valves. The Philadelphia Electric Company employs reducing valves and plugs in order to permit the withdrawal and limitation of samples without contamination of the oil. (Table II, Part III, 25-26.)

On circuit breakers most companies use the existing sampling connections installed by the manufacturers. A few companies add necessary connections when not provided by the manufacturers. The Ohio Public Service Company has mounted sampling devices at the top of the oil level and also near the bottom of the tank. Sampling cocks one-quarter inch in diameter are used by the Public Service Electric & Gas Company (New Jersey) and the Southern California Edison Company. (Table II, Part III, 27-28.)

Apparently most of the oil sampling connections on transformers and circuit breakers have been suitably located, since only a comparatively few companies offer any suggestions for changes or improvements. The Philadelphia Electric Company believes that the valve connection should be located on the tank itself and not on the drain pipe if a representative oil sample is to be obtained without undue wastage. All the companies offering suggestions emphasize the fact that sampling valves should be located at the lowest point of the tanks in order to show the presence of any sediment which may exist. (Table II, Part III, 29-30.)

APPENDIX I

OPERATING INSTRUCTIONS OF CHARLES H. TENNEY & COMPANY

(Abstracted for the Purposes of this Report)

All transformers shall be regularly inspected. All subway transformers, and all others rated at 13,200 volts or more and of 50 kv-a. capacity or more, shall, at least once each year, have their oil filtered by means of standard equipment of a type approved by the Engineering Department. Those of less than 50 kv-a. capacity and of less than 13,200 volt rating shall be inspected at least once in five years, and shall have their oil tested, and changed if necessary. When an excessive amount of water or sludge is found in oil upon filtering, the Engineering Department shall be notified immediately so that a special investigation can be made. At times of inspection terminals and connections shall be carefully examined and left in proper operating condition.

Whenever the results of tests of oil from breakers or transformers indicate low dielectric strength or the presence of sudge, the oil shall be refiltered with the approved equipment until brought up to the standard established by the Engineering Department.

APPENDIX II

ENGINEERING LETTER FROM THE ELECTRIC BOND & SHARE COMPANY

(Abstracted for the Purposes of this Report)

The filter press process of oil drying and purifying is the older one and has been in successful use for a number of years. It consists essentially of a motor-driven pump pressing the contaminated oil through a series of blotting papers. Recent improvements in design, notably the additions of an air bell for the testing of leaks in the suction piping, which bell can also be applied to existing presses, render the oil less subject to aeration during the operation.

The filter press process, nevertheless, still has several disadvantages. One of these arises from its slowness of operation, it having been our experience that the 1800 g.p.h. press will average only approximately 400 g.p.h. over extended periods of operation, due to the clogging of the blotting paper and the time consumed in changing the paper. The frequent renewal of blotting paper necessitated is in itself a disadvantage since the oil will not be successfully dehydrated if blotting paper is allowed to remain in the press after the paper has become too moist. Another difficulty experienced is in keeping the oil pressure low enough to prevent puncture of the blotting paper and consequent passing of contaminated oil.

The centrifugal process of oil drying and purifying is more recent in its application to insulating and cooling oils, although it has been used successfully for some time in the purification of lubricating oils. It consists essentially of a revolving vessel which whirls the oil against discs and permits the impurities to be separated through the operation of centrifugal force. A recent improvement is the addition of an aeration bowl, which insures the passing of the oil from the separator with no more entrapped air than it had when entering. This process permits of the combined centrifugal and chemical treatment by which impurities affecting the chemical and physical characteristics of the oil are eliminated by reagents at the same time that carbon and water are removed by centrifugal action. The method is fully described in "Purifying Circuit Breaker Oil," by Lee Hinchman Clark, Sept. 19, 1925, issue of the *Electrical World.*

The centrifugal process also has its disadvantages. It will not remove finely divided carbon particles held in suspension in the oil, which require for their removal either the filter press or a chemical treatment. It is necessary to heat the oil to approximately 100 deg. fahr. for the best results with the centrifuge. The apparatus for the centrifugal process costs approximately twice as much as the apparatus of the same actual capacity for the filter press process.

A comparison of the two methods based upon the information available seems to indicate that the filter press process is best suited to the reconditioning of lightly contaminated oils, and that the centrifugal process makes the best showing when used for heavily contaminated oils, where its greatest speed in operation has its maximum effect. The centrifugal process is admirably suited for the rapid purification of transformer oils and others containing large quantities of water. It is not, however, as well adapted for the purifying of circuit breaker oils and others which have considerable carbon therein.

Dependence solely upon the centrifugal process alone is scarcely to be recommended at this time, although a combination of the two methods should produce very satisfactory results; for example, passing oil which shows the greatest contamination in finely divided carbon first through the centrifuge and afterward through the filter press.

APPENDIX III

OIL SPECIFICATION OF THE COMMONWEALTH EDISON COMPANY

(Abstracted for the Purposes of this Report)

1. GENERAL: The oil furnished in accordance with this specification will be used in oil circuit breakers and transformers and other electrical apparatus. (Distribution Division Spec. S1950 has same requirements).

2. FLASH POINT: The flash point shall not be less than 130 deg. cent. (266 deg. fahr.). Test Method:—A.S.T.M. Standards, 1927, D92-24, pages 404-408.

3. FIRE POINT: The fire point shall be not less than 149 deg. cent. (300 deg. fahr.). Test Method:—A.S.T.M. Standards, 1927, D92-24, pages 404-408.

4. VISCOSITY: The viscosity shall be not more than 65 sec. at 37.8 deg. cent. (100 deg. fahr.). Test Method:—A.S.T.M. Tentative Standards, 1927, D88-26, pages 427-432

5. EVAPORATION: The evaporation loss shall be not more than 4.0 per cent by weight. Test Method:—Five cubic centimeters of the oil contained in an open dish, 2.5 in. in diameter and ⅝ in. deep, shall be heated in an oven at a temperature of 65-75 deg. cent. (149-167 deg. fahr.) for 8 hr.

6. POUR POINT: The pour point shall be not above —35 deg. cent. (—31 deg. fahr.). Test Method;—A.S.T.M. Tentative Standards, 1927, D97-27-T, pages 390-396.

7. NEUTRALIZATION NUMBER: There shall be required not more than 0.1 milligram potassium hydroxide to neutralize 1 gram of the oil. Test Method:—A.S.T.M. Tentative Standards, 1927, D188-27-T, pages 418-420, Method A, Section 4.

8. FREE AND CORROSIVE SULPHUR: The oil shall not contain free sulphur or corrosive sulphur compounds. Test Method:—A.S.T.M. Standards, 1927, D117-27, page 800.

9. MINERAL ACIDS: (Chlorides and Sulphates) The oil shall be free from mineral acids (Cl or SO_3). Test Method:—A.S.T.M. Standards, 1927, D117-27, page 800.

10. SLUDGE: The oil shall comply with the following sludge test requirements.

10.1. A deposit of sludge shall be not visible until a sludge test in accordance with the American Life Test method has been continued for at least 20 days on samples taken at the refinery, and for at least 12 days on samples taken from oil delivered to purchaser in drums or tank cars. Test Method:—A.S.T.M. Proceedings, June 1927, pages 541 to 549.

10.2 The amount of sludge obtained when a sample of the oil is heated to 85 deg. cent. (185 deg. fahr.) for 55 days in the presence of copper and iron shall not exceed 0.020 per cent by volume on samples taken at the refinery and shall not exceed 0.050 per cent by volume on samples taken from oil delivered to purchaser in drums or tank cars.

Test Method:—375 cubic centimeters of the oil under test is filtered into a clean one pint mason fruit jar, which has been cleaned according to procedure described in test method for paragraph 10.1 above. A piece of copper 8 x

1.25 x 0.16 cm. and a piece of transformer iron 8 x 1.4 x 0.04 cm. are thoroughly cleaned with emery and washed with acetone and with the oil to be tested, and then placed in the oil sample.

Test samples are placed in an oven having its temperature maintained within 2 deg. cent. of 85 deg. cent. The position of the samples in the oven is shifted each week to neutralize inequalities of temperature in the oven. A stream of air is passed into the oven through a wash bottle containing insulating oil.

After being heated for 55 days, the samples are removed from the oven and allowed to stand for 4 days at room temperature. The oil is then thoroughly mixed with the sludge and poured into a clean container. The test jar is washed with 10 cubic centimeters of acetone until any sludge film in the jar is dissolved, then 10 cubic centimeters of the tested oil is added and the acetone expelled by heating at 70 deg. cent., and then the residue of oil and sludge is added to the main test sample.

One hundred cubic centimeters of the sample is then placed in a graduated centrifuge tube and subjected to centrifuging at 1400 r.p.m. for 90 min.

There is practically no increase in the volume of sediment with centrifuging continued for more than 90 min., but occasionally a clear line of demarcation between sludge and oil will not be obtained in this time, and contrifuging is continued for 30 min. intervals until a clear separation is obtained. The volume of sludge in cubic centimeters is numerically equal to the percentage, by volume, of sludge in the oil at the end of the heating period.

11. DIELECTRIC STRENGTH: The dielectric strength of the oil shall be not less than 25 kilovolts. Test Method:—A.S.T.M. Standards, D117-27, pages 801-803.

12. SUBMISSION AND TEST OF SAMPLES: A 1 gal. sample of the kind of oil that is proposed to be furnished shall be delivered to the purchaser at the testing department. If the sample meets the specifications in all particulars, oil of the same quality can be shipped as instructed. This does not require that the oil supplied be of the same lot as the original sample, but it does require that the oil supplied be made in accordance with the same specifications and subject to the same control and inspection to have the same characteristics as the original sample.

Each shipment of oil will also be sampled and tested by the purchaser, including the sludge tests, and shipments not meeting these specifications will be rejected and shall be removed by the vendor. The vendor shall pay all expenses in delivering and removing the rejected oil.

13. SHIPMENT: Insulating oil shall be shipped in oil-tight steel drums, unless otherwise specified. Each container shall be legibly marked with purchase order number and vendor's name. Each drum which can be returned to the vendor for credit shall be marked with a serial number, either by figures stamped in relief on the barrel head or by figures stamped on a brass plate and the plate brazed to the barrel head. The figures shall be at least ½ in. high and preferably at least 1 in. high.

APPENDIX IV

OIL SPECIFICATION OF THE NEW YORK AND QUEENS ELECTRIC LIGHT AND POWER COMPANY

(Abstracted for the Purposes of this Report)

1. SCOPE: The oil furnished in accordance with this specification will be used in all oil immersed electrical devices for purposes of insulation and cooling. This specification will not cover oils used in cables and potheads.

The insulating oil shall be a pure mineral oil from which inorganic acids, alkalis and free sulphur shall be absent.

Oil purchased under this specification shall conform to the following requirements as determined by the test methods specially noted.

2. FLASH POINT: The flash point shall be not less than 130 deg. cent. as determined by test method D-92-24, A.S.T.M. Standards, 1927, Part II, page 404.

3. FIRE POINT: The fire point shall be not less than 150 deg. cent. as determined by Test Method D-92-24, A.S.T.M. Standards, 1927, Part II, page 404.

4. POUR POINT: The pour point shall be not higher than —40 deg. cent. (—40 deg. fahr.) as determined by Test Method D-97-27, T, A.S.T.M. Tentative Standards, page 390.

5. VISCOSITY: The viscosity shall be not greater than 50 seconds Saybolt at 37.8 deg. cent. as determined by Test Method D-88-26 A.S.T.M. Standards, 1928, page 427.

6. NEUTRALIZATION NUMBER: There shall be required not more than 0.05 milligram of potassium hydroxide to neutralize 1 gram of the oil as determined by Test Method D-188-27-T, A.S.T.M. Tentative Standards, 1928, page 431.

7. MINERAL ACIDS (Chlorides and Sulphates): The oil shall show the absence of mineral acids (chlorides and sulphates) as determined by Test Method D-117-27, A.S.T.M. Standards 1928, page 800.

8. FREE AND CORROSIVE SULPHUR: The oil shall not contain free sulphur or corrosive sulphur compounds as determined by Test Method D-117-27, A.S.T.M. Standards, 1928, page 800.

9. SLUDGE: A deposit of sludge shall not be visible until a sludge test has been continued for at least 18 days in accordance with the Snyder Life Test as published in Appendix to Report of Committee D-9, 1927 Proceedings, A.S.T.M., Part I, page 541.

10. RESISTANCE TO EMULSIFICATION: The precise R.E. number of the oil shall not exceed 25 sec. as determined by the Standard Method of Test for Steam Emulsion of Lubricating Oils, Serial Designation D-157-27, A.S.T.M. Standards 1927, Part II, page 414.

11. DIELECTRIC STRENGTH: The dielectric strength shall be not less than 22 KV. as determined by Test Method D-117-27, A.S.T.M. Standards, 1928, page 801.

12. SAMPLING METHODS: The oil sampling procedure for these tests shall conform to the methods outlined in D-117-27, A.S.T.M. Standards, 1928, page 796.

13. DETERMINATION OF QUANTITIES: Sixty degrees Fahrenheit (60 deg. fahr.) is established as the normal temperature for all oil to be delivered under this specification. Deductions shall be made and additions shall be made to the apparent quantity of oil contained in any delivery in accordance with the Standard Abridged Volume Correction Table for Petroleum Oils, A.S.T.M. Serial Designation D-206-25, A.S.T.M. Standards 1927, Part II, page 351. The temperature reading of the oil shall be made at time of volume measurement.

14. ACCEPTANCE TESTS: Proposed bidders shall submit a 2 quart sample in a glass container of the oil proposed in the bid.

Each shipment of oil will also be tested by the Purchaser after sampling at point of delivery. Oil which fails to comply with any one or all of the limits specified, will be rejected and must be removed by the Vendor, who shall pay all expenses of delivery and removing the rejected oil.

APPENDIX V

OPERATING INSTRUCTIONS OF THE PHILADELPHIA ELECTRIC COMPANY

(Abstracted for the Purposes of this Report)

Transformer oil shall be used only for transformers; circuit breaker oil shall be used only for oil circuit breakers.

All supply lines shall be kept filled with clean oil.

Dirty oil tanks may be used for either dirty transformer or dirty circuit breaker oil, but only one grade of oil is to be deposited in the tanks at one time. All dirty oil deposited in the tanks shall be immediately purified and returned to its respective clean oil storage system in order that the dirty oil tanks may be available at all times for oil of either type. It is extremely important that oils of different grades be not mixed except as noted below.

When the dirty oil drain header has been used, it shall be drained as dry as possible in order to prevent the mixing in the system of oils of the two classes. Operation of the purifier pump will clear this header. All oil drawn from the header when draining shall be purified and returned to clean breaker oil tanks, not to dirty oil tanks. After the header has been drained, it may be used for the emptying of either transformers or oil circuit breakers.

Before the 100-g.p.m. pump shall be used to fill with clean oil a transformer or oil circuit breaker, it shall be washed out by having run through it and out to the dirty oil tanks a small quantity of the oil to be pumped. The oil used for washing the pump shall be immediately purified and returned to the clean breaker oil tanks.

APPENDIX VI

STATEMENT BY THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY

(Abstracted for the Purposes of this Report)

Storage tanks may be placed either entirely above ground or entirely below ground. When placed below ground they should not be embedded in concrete, but should be arranged with plenty of space on all sides for inspection and for access of fresh air. The question of whether explosive vapors will accumulate in such an underground pit need not be considered since insulating oils are far different in this respect from such materials as gasoline, benzine and other volatile liquids. Wherever tanks are embedded in concrete, it is practically impossible to keep the oil free from an accumulation of moisture, because the temperature of the tank walls always lags behind the temperature of the oil sufficiently to permit the formation of dew on the inside surface of the tank, above the oil level.

Oil tanks should not be arranged with their axes exactly horizontal and a small drainage point should be provided at the lowest elevation, in order to permit of the drawing off of any sediment and moisture which may settle at the bottom. The incoming oil should enter near the surface, if possible, so that any such sediment will not be appreciably disturbed and will not be mixed with the oil to any great extent. For the same reason, the oil outlet should also be a certain distance from the bottom.

When oil tanks are arranged with their axes vertical, it is possible to have both the inlet and outlet pipes some distance above the bottom without involving a large volume of oil, especially when the ends of the tanks have considerable convexity.

Although the lagging of tanks may be of some assistance, it is doubtful whether the extra expense is ever warranted. In some cases, where it is easy to do so, tanks may be heated by steam coils. There is, however, some danger of the formation of a deposit on account of the extreme temperature which may exist at the surface of the source of heat, this temperature being quite likely to be high enough to cause sludging in any known insulating oil.

Piping in general should be so arranged that there will be no pockets of dead oil, accumulated air or moisture. If possible, in cases where both dirty and clean oil must be handled, separate pipes should be provided, especially in the case of circuit breaker oil. If impossible, means should be found for completely flushing out the piping with clean oil after carbonized oil has been passed through it and before reconditioned oil is returned through to the breaker itself. It may at times be advisable, even though expensive, to furnish parallel pipe lines, connected to the breaker tanks by three-way cocks; such an arrangement allowing the use of the dirty pipe line for the emptying of a tank which contains carbonized oil and the use of the other line for refilling the same tank with clean oil.

The capacity of oil reconditioning apparatus selected should depend entirely on whether or not it is more economical to be able rapidly to handle the oil in emergencies or to be required to have a large gang of men waiting while apparatus of small capacity is being used to empty, clean and refill apparatus tanks. It must always be remembered that a saving in the capacity of filtering or centrifuging outfits may be absorbed in a very short time if, in emergency, apparatus cannot be restored to service promptly, and a large crew is, therefore, kept waiting for an appreciable length of time. It should also be borne in mind that the interest on the capital invested in a large filtering outfit is likely to be much less than the cost of having important equipment out of service for any considerable length of time.

APPENDIX VII

POLICY ON THE UTILIZATION OF ELECTRICAL INSULATING OILS OF THE DUQUESNE LIGHT COMPANY

(Abstracted for the Purposes of this Report)

1. The departments of the Duquesne Light Co. purchasing, stocking and using electrical insulating oils shall observe the procedure outlined, effective Dec. 1, 1927.

2. New Oil Purchases and Stocks shall include:
   a. Wemco C oil—Westinghouse Electric & Mfg. Co.
   b. G.E. No. 21-C oil—General Electric Co.
   c. G.E. No. 6 oil—General Electric Co.

3. Application of New Oils shall include:
   a. Wemco C oil shall be used in all Westinghouse company oil submerged electrical equipment, both indoor and outdoor, and for replacement in General Electric Company indoor and outdoor transformers, induction voltage regulators and constant current transformers. Wemco C oil shall not be used in General Electric Co. indoor and outdoor circuit breakers.
   b. G.E. Co. No. 21-C oil shall be used in General Electric Company outdoor circuit breakers; in indoor breakers of the following types only: FK 130—FK 230—FHK 130—FHK 230, and in D. and W. Fuse Cutouts.
   c. G.E. Co. No. 6 oil shall be used only in General Electric Company indoor circuit breakers, Types FK 130—FK 230—FHK 130—FHK 230 excepted.

4. Reconditioned Serviced Oil Stocks shall include:
   a. 1. Serviced transformer oils, low-pour test as Wemco C, Transil No. 10-C.
      2. Service transformer oils, high-pour test as Wemco A, Transil No. 10—Pittsburgh.
   b. 1. Serviced circuit breaker oil—Wemco C.
      2. Serviced circuit breaker oil—G.E. No. 21-C.
   c. Serviced circuit breaker oil—G.E. No. 6
   d. Mixed serviced oils for use only in distribution transformers of 50 kv-a. and under for overhead line work.

5. Application of Reconditioned Serviced Oils shall include:
   A. From Transformers:
      1. Wemco A and G.E. 10 oils serviced in Westinghouse, General Electric and Pittsburgh transformers, indoor type, after reconditioning may be reused only in indoor transformers supplied by the Westinghouse, General Electric and Pittsburgh Companies.
      2. Pittsburgh Oil serviced in Pittsburgh Transformers after reconditioning may be reused only in Pittsburgh Transformers.
      3. Wemco C and G.E. 10-C oils which have been serviced in transformers may be reused for indoor or outdoor service in any manufacturer's transformers.
      4. Wemco A, G.E. 10 and Pittsburgh oils must not be used for make-up oil in outdoor transformers, which contain Wemco C or G.E. No. 10-C oils.
      5. Note: It will be the policy of the company to retire gradually from service Wemco A oil, G.E. Transil No. 10 and Pittsburgh oils, and in their placed to supply Wemco C oil, either new or serviced.

   B. From Circuit Breakers and Outdoor Regulators:
      The reuse of reconditioned serviced oils in circuit breakers and regulators shall conform to its original application in the apparatus specified.

Oil	Original Application	After Reconditioning
Wemco C	W. E. and M. Co. Circuit Breakers, indoor and outdoor	W. E. and M. Co. Circuit Breakers, indoor and outdoor
Wemco C	W. E. and M. Co. Regulators, outdoor	W. E. and M. Co. Regulators, outdoor
G. E. No. 21-C	G. E. Co. Circuit Breakers, outdoor only	G. E. Co. Circuit Breakers, outdoor only
G. E. No. 6	G. E. Co. Circuit Breakers, indoor only	G. E. Co. Circuit Breakers, indoor only

   C. From Lightning Arresters:
      Oils serviced in lightning arresters shall not be reused for any other service.

6. Removal of oils from service shall be made when the values do not conform as follows:

Determining Values	Circuit Breakers	Transformers Outdoor Regulators
Dielectric strength min. kv.	18.0	18.0
Suspension	visible	visible
Pour test not higher than deg. C.	—25*	—25*

*Applies to outdoor circuit breakers and regulators.

7. Reconditioning of oils may be made by a centrifuge, by blotter type filter press or by both as follows:
   a. Oils removed from outdoor circuit breakers will be reconditioned and reclaimed for reuse in outdoor circuit breakers when the pour test is below minus twenty-five (—25) deg. cent.
   b. Oils removed from outdoor regulators will be reconditioned and reclaimed for reuse in outdoor regulators when the pour test is below minus twenty-five (—25) deg. cent.
   c. Oils removed from transformers will be reconditioned and reclaimed for reuse in transformers when they show no evidence of mixture of circuit breaker and transformer oils.
   d. Oils removed from transformers showing evidence of mixture of circuit breaker and transformer oils will be reconditioned and reclaimed for reuse only in distribution transformers of 50 kv-a. and under on overhead line work.
   e. Oils removed from any other apparatus and showing evidence of mixture of circuit breaker and transformer oils will not be reconditioned, and will be permanently rejected from service.

8. Disposition of Oils.
   Oils removed from equipment and conforming to the intended service, when reconditioned in the field shall be restored to similar service. Oils removed from equipment for reconditioning at the Central Oil Reclamation Plant at Manchester shall be handled in containers provided, and shall not be mixed in the field. All such shipments shall be marked showing the previous service of the oil. Oils permanently rejected shall be disposed of by the Stores Department.

OUTLINE OF FUNDAMENTALS OF SYSTEM INTERCONNECTION

Introductory Comment

Probably no single engineering feature of the industry is of so much interest to utility executives as the subject of interconnection. Certainly in no other single way can such sweeping benefits and signal economies be effected with minimum capital expenditure as by a sane and reasonable process of neighborly cooperation.

While the report does not attempt a universal solution, it does clearly and comprehensively state the problems involved in interconnection, outlines the methods of attack and should serve as a valuable guide to procedure in approaching any interconnection project. The report does not blithely dismiss the difficulties that are bound to arise. It does, however, very clearly indicate that they are not different in character from the problems which are met and solved internally in any of our large systems.

It is suggested in the report that it is possible to operate utilities under separate ownership to effect the same economies that would result were the ownership common. Granted that both parties to an interconnection must benefit and that the benefits may be either in dollars or "in kind," and granted further that both parties are approaching the problem with openness of mind, there would seem to be no essential difficulty in making such common adjustments as are necessary to contractual understanding. Executives will appreciate that a meeting of minds as between neighboring utilities need not be any more difficult than is mutual understanding and agreement between the varied interests internal to each.

Engineers will welcome this report as an index and outline of procedure. Executives will find it an excellent summary of the questions they may wish to ask of their engineers.

JOHN C. PARKER
Vice-President in Charge Engineering
Brooklyn Edison Company, Inc.

OUTLINE OF FUNDAMENTALS OF SYSTEM INTERCONNECTION

STATUS OF PROBLEM—ITS IMPORTANCE

The purpose of this report is to present the general considerations involved in the planning and execution of system interconnections. Interconnection standards, commercial and accounting as well as technical, have not been formulated as a whole, and it is desirable that they be developed in order to provide for coordinated power development and distribution. The increasing dependence of industrial and community life on electric utility service makes reliability of supply a prime consideration. The added protection from possible interruption to service by a considered policy of interconnection is correlated with the growth of systems and economical use of capital funds. The diverse ownership and control of utility properties should not interfere with a proper interweaving of independent power systems, where this can be brought about by a clearer understanding of the problem and the adoption of cooperative policies.

I—NATURE AND PURPOSE OF INTERCONNECTION

Interconnection as Distinguished from Transmission

Interconnection is the joining together of separate power systems in order to provide for interchange of power, to the end that mutual protection of service and greater combined economy of operation may be obtained.

The transmission of electric power from the source to a distribution center by direct transmission lines has been developed to the point where standards of practice are quite generally understood and reasonably applied. This is not classified as an interconnection in this report, although transmission practices are, in general, applicable to interconnection.

Interconnection—Normal Operation and Emergency Use

1. For Continuity of Service

If a connection is proposed to insure continuity of service, a thorough investigation of the system is required to determine the need of power and its availability. An interconnection made for the reason of continuity of service is usually of the emergency type and may be made either for protecting the system as a whole, or for protection of a portion of the system which is not otherwise adequately supported. For instance, two densely loaded areas, which are very close to each other and without appreciable diversity, desire insurance in the form of a high capacity tie against such a catastrophe as the loss of several large units at once. This tie should be terminated at high capacity buses in each system, or at load centers where the required amount of power could be readily absorbed. Another example would be a lightly loaded substation fed by a single transmission line and located closer to another system than to its own source of supply. A small capacity tie from the other system gives emergency service. If the two systems are not already in synchronism, the emergency tie should normally be operated open.

2. For Reduction of Fixed Charges

In order to determine whether an interconnection is justifiable on the grounds that it results in a reduction of the fixed charges in either or both systems, an investigation of the load diversity, generator reserve diversity, transmission reserve diversity, construction program diversity and financial diversity is required. The connection may be justified on any one or all of these items.

(a) *Load Diversity.* A careful estimate of load diversity should be obtained by making a comparison of the existing and future loads of the systems to be connected and by investigating the hourly, weekly and seasonal saving in generating capacity comparable with the cost of the interconnection.

(b) *Generator Reserve Diversity.* While the proper amount of spare generating capacity varies greatly in different localities, a detailed study might result, for instance, in a decision by the engineers representing the two systems to maintain only 12 per cent spare generator capacity after interconnection, where before 15 per cent was maintained. Obviously, there is a critical limit to this diversity, and the proper value will be determined only by experience.

(c) *Transmission Reserve Diversity.* Occasionally two systems are so located geographically that a tie between them will act as a transmission spare to a portion of either. In such a connection, synchronizing capacity should be very carefully investigated.

(d) *Construction Program Diversity.* This type of diversity becomes of importance through the greater economy of an extensive construction program which can be planned and carried out with less disturbance to operating routine. A typical example of construction program diversity is the case where companies A and B each grow at the rate of 10,000 kw. a year and find that the most economical generator unit for the combined systems is 20,000 kw. They interconnect, A installing generating capacity one year, and B the next year.

(e) *Financial Diversity.* Occasionally two contiguous systems may be interconnected to obtain the financial advantage which may accrue through the ability of one company to supply the necessary construction at lower cost.

Publication No. 289-60, Serial report, Electrical Apparatus Committee.

3. Reduction of Operating Costs

Besides the reduction of operating costs arising from less installed capacity, it is necessary to determine whether at times one system will have available more economical generating equipment than another system would normally be operating at that time. If so, an additional reduction in operating costs can be obtained through interchange. Such interchange connections find their greatest use in systems composed of both all-steam and all-hydro stations, although variations in the costs of either all-steam or all-hydro systems may establish such a connection. Diversities as between water supply, either condensing or water power, coal supply, etc., are likely to enter into the analysis of this problem.

4. Complications of Interconnection

(a) *Operating Routine and Divided Responsibility.* As an offset to these benefits of interconnection, there are the disadvantages of greater complication in operating routine and divided responsibility which can only be reduced to a minimum by agreement between the different companies and by unified control.

(b) *Operating Disturbances.* The possibility of operating disturbances affecting a much larger territory than with independent operation must also be taken into account, and methods adopted by automatic and manual control to prevent any jeopardizing of continuity of supply to the entire region served.

(c) *Reliability of Interconnection Facilities.* Any saving of generator capacity resulting from interconnection involves a partial dependence of one system on the other. The reliability of the interconnection facilities must be such that they do not introduce a net hazard.

II—CONTRACTUAL RELATIONS

Operating and Engineering Agreement

Agreement as to the engineering features of the interconnection, the division of costs and charges of the actual interconnection facilities as well as costs of reinforcing existing facilities, contingent items, the construction forces to be employed and responsibility for the work should be definitely established. The form of contract will, of course, be dependent upon local conditions and may vary considerably due to variations of the fundamental factors underlying the interconnection; for example, an operating agreement, when made to provide for more reliable service, must differ considerably from a contract which has as its basis a reduction in fixed charges. Operating and maintenance plans for normal and emergency service as affecting the different companies interested may form a part of such a contract, or be covered by separate agreements.

Load Dispatching

Complete understanding and authority to insure effective cooperation must be set up in the arrangements for load dispatching which should preferably be centralized.

Adjustment of Interests

The agreement must be sufficiently inclusive to provide for a harmonious adjustment of conflicting interests and flexible enough to permit adjustment of these differences when they develop, with provision for arbitration. This may be obtained by an operating committee with a personnel having authority to settle disputed questions. It may be found advisable, if daily power interchange is contemplated, to incorporate an independent operating company, under the control of the contracting companies, to control and operate the combined interconnection facilities, to supervise the interchange of power and in general to serve as a coordinating medium.

Records

The agreement should provide for uniform systems of records pertaining to the execution of the contract.

III—ORGANIZATION FOR COOPERATIVE ANALYSIS

To investigate a proposed connection, it is advisable to have an organization set up which has in mind the joint responsibility of the companies and the broad scope of the work to be accomplished. This can usually be effected by dividing the work into two portions and forming a committee or group to handle each.

The first group would study the loads and diversities, existing and forecast, of the systems to be interconnected, the economies to be obtained through the interconnection, and the general benefits to be derived.

The second group is primarily interested in the design of the physical plant needed to accomplish the purposes enumerated by the load and diversity group. Its chief interest would lie in such things as the design of the substations and transmission lines; the selection of line routes; the determination of the regulation of the lines, the means for controlling the flow of power, the synchronizing power required to keep the two systems in parallel operation, and the protection needed; and the calculation of short circuit values so that equipment adequate for future use may be provided. Complete construction and operating cost estimates on this initial interconnection program must be made with due regard to the effect on these costs of future additions to the interconnection plant.

IV—IMPORTANT ENGINEERING PROBLEMS INVOLVED IN INTERCONNECTION

Load Forecasting, Peak Loads and Load Factors

The first technical step in the consideration of a proposed interconnection project is the analysis of the system loads, regional and local, over a period of past years with a forecast of the expected growth of each section of the region to be served. The economic factors affecting the growth of the different industries and communities served would be considered, and the anticipated loads for successive future years would be drawn up. The division of load between power sources, transmission lines and substations, with predicted peaks, power factors and load factors, would then be studied and the effect on station operating costs determined. The interconnection and future construction program would be based on the derived load curves. Operating costs and fixed charges for successive future years would be set up to show development under an interconnected program as compared with the independent development of present systems.

System Stabilty

A study of system stability, often one of the most important fundamentals to be considered in the development of interconnected systems, should be made for both static and transient conditions.

The static stability or the operation of the system under normal steady load conditions can be calculated with reasonable accuracy from machine, transformer and line characteristics and a study of the voltage regulator, machine governor and exciter operation. The static power limit may be increased by changes in these automatic controls and by the use of low reactance synchronous machines. The operating limitations due to static stability are important only in considering the system under conditions of transmission line outages impairing the strength of the combined system ties.

The transient stability under fault conditions, and load relations under the various system disturbances which may occur due to switching operations and breakdowns in apparatus and lines, should be studied carefully in its functioning. Considerable experimental and operating data have been obtained from present interconnected systems and artificial test systems, which indicate new methods of approach in making such a study. The subject of stability is so important, involves so many considerations, and its state of development is such that expert advice should be obtained with a view to determining the effect on stability of such factors as:

Switching operations.
Normal and abnormal variations in load.
The nature of the load.
The nature, frequency, duration and location of faults.
Ground resistance.
Reactance in the system.
Excitation characteristics.
Time characteristics of relays and circuit breakers.

Load Control

The interchange of load over interconnection ties necessitates the ability to control the transmission of load at will, in either direction, and at any hour of the day. The problem of load control increases in complexity with the increase in diversity of interconnecting tie characteristics. The importance of this problem is emphasized as careful study is required to assure proper load control, particularly where the interconnection involves more than one point of tie.

The question of variation in voltage levels between the different parts of the system where tie lines are interconnected, and the differences in electrical constants of multiple tie lines, must be studied in relation to the circulating and charging currents, and a proper solution found for the conditions imposed. The use to be made of voltage regulators, transformers with tap changers, reactors, etc., must be determined in order to obtain satisfactory operating conditions and load control. The introduction at the proper location on the system of synchronous condensers of the required capacity must be studied, together with the use of auto transformers with tap changers, induction regulators or synchronous boosters.

The general solution of these problems is now being found in the solution of similar problems in present individual power systems. These internal system interconnections may be of a more complicated nature than interconnections between large systems.

Protection Schemes

When systems differ radically in their protective features, such as relay methods, reactors and methods of grounding, it may be necessary to make changes to bring the systems into harmony with each other before interconnection for other than emergency service can be made effective.

The requirements of the protective system of an interconnection are, in general, as follows:

It should clear faults quickly to prevent loss of synchronism; must afford protection in case of single line as well as parallel line operation; and must afford proper protection for power flow in either direction.

It should permit flexibility of operation, use of transfer breakers, dual switching, etc.; must permit complex system connection without necessitating system revisions; should afford bus protection: and must be reasonably economical.

In most protective schemes time delay is objectionable and should be reduced to a minimum or eliminated, where possible. Therefore, some form of balanced or differential protection may be the solution. Relays of the usual overload type, such as are used with selective settings, on the fringe of the system, cannot be used for the major positions because of excessive time delay.

Balanced protection may be divided into two groups; namely, balanced current and balanced power. The current differential may be a series balance involving pilot wires or a parallel balance where multiple circuits are concerned. Balanced power may, likewise, appear as parallel balance for multiple lines, or a series balance using pilot wire or its equivalent, such as carrier current, which is still in the experimental stage. Balanced protection has its limitations with respect to bus protection, flexibility of system operation, and the condition of a single line in operation. Moreover, it places limitations on system connections. There are cases, however, in which it must be used.

A very promising solution, as far as clearing of fault is concerned, lies in the use of differential bus protection and pilot wire line protection. Practically, however, the latter can be applied only to the shortest sections.

Where time must be relied upon for selectivity, the inverse characteristic is preferable. This is now more or less universal in this country. The ohmic or impedance relays, which have their inverse nature accentuated by the drop in voltage, appear to meet the requirements more closely than any other available device. Bus protection, quick clearing of faults and single line protection are secured. As the system grows more complex, increased time for operation is not required, nor does the relay place limitations on the system connections. The time required for clearing faults does not become cumulative. However, on very short lines with high impedance to the sources of power, discrimination cannot be secured by the impedance relay and pilot wire or balanced protection must be used.

Load Dispatching Facilities

Successful joint operation requires that adequate facilities be provided for load dispatching. It is necessary for the load dispatcher to know, or be in a position to ascertain, at all times, the loads and available generating capacities of each system and, in some cases, of each station and substation. He must know the loading and physical condition of the circuits and those which are out of service. This implifies unified control and authority in matters of generation and transmission of power. However, in some cases, authority will be preferably divided between the dispatchers of the systems involved. Adequate communication facilities, both normal and reserve, in the form of telephone lines, radio or carrier current communicating routes, must be provided.

The load dispatcher should have as complete information as possible on weather forecasts over the different parts of the system, on construction and repair programs which affect operation of generating plants and lines, and on abnormal loads to be expected on different parts of the system.

Metering and Apportionment of Losses

The metering of power, together with recording of kilowatts, volts and kilovolt-amperes, to show the interconnection interchange of loads and characteristics, must be studied carefully and responsibility for meter accuracy assigned. A plan for apportioning losses between the different systems should be decided upon.

Standardization of Engineering Practice Prior to Interconnection

1. VOLTAGE

The question of voltage standardization has been taken up actively in this country, and progress is being made to obtain the many economic advantages which reasonable standardization will procure. It is particularly important as a fundamental in connection with the development of interconnection to analyze carefully the many conflicting influences which bear on this question of voltage standardization.

The simplification of the interconnected systems by reducing the variation in voltage levels to a minimum must be realized to prevent interference with flexibility in transmission, regulation and load control. This is particularly necessary in this country where transmission distances are increasing as more of our available water powers are developed.

2. PHASE ANGLE

It is desirable from the standpoint of future interconnection for neighboring systems to establish a definite policy in star to delta transformations. The policy of making the connection with the delta 30 deg. lagging relative to the star seems to offer the greater advantage on account of facility in starting up synchronous apparatus.

3. PROTECTION

Reasonable standardization in system protective features, such as relay systems, reactors, and methods of grounding, at the present time, will permit power systems to gradually apply these standards at a nominal cost while additions and changes are made, and thus avoid excessive changes and expense when interconnection is found to be desirable. This standardization should not be difficult, nor should it interfere with flexibility in the development of power systems.

4. CONSTRUCTION DETAILS

The standardization of construction details is desirable from the standpoint of reducing manufacturing costs and in keeping maintenance and emergency stock at a minimum. It assists operation by familiarizing the operating and maintenance forces with standard arrangements of equipment. Transmission line crossings over telephone and telegraph lines, power lines and railroad rights-of-way are usually built in accordance with accepted practice and, in general, more rugged construction is secured. This increases the reliability of the system, as a whole, after interconnection is accomplished.

V—SYSTEM PLANNING PRIOR TO INTERCONNECTION

It is desirable that, so far as practicable, interchange of ideas should be accomplished between companies so located that their future relations will probably involve interconnections, although such interconnections may not be imminent nor even a seriously considered problem at present. This interchange of ideas may take the form of very informal conferences between the responsible engineers of the adjacent companies or through a somewhat formal joint system planning committee, or through regional groups who meet for the general study of engineering problems without relation to specific interconnection problems. An example of the advantage of such cooperation is that of companies in contiguous territory, perhaps having no immediate justification for considering interconnection, but each developing a new transmission system of its own, one say at 110,000 volts and the other at 132,000 volts. This would lead to a voltage difficulty when interconnection is seriously complicated, whereas joint system planning conferences might have prevented such a situation.

D. C. SUBSTATION DESIGN PRACTICE

This report presents in a condensed form the principal features of design of twenty-seven direct-current substations supplying Edison or railway loads. The data are presented along the general lines found useful in two preceding reports on alternating-current substation design, "A. C. Substation Design Practice," Publication No. 25-44, *issued in July,* 1925, *and "A. C. Substation Design Practice—*1927,*" Publication No.* 278-39, *issued in April,* 1928.

The report is divided into four sections: (1) *Automatic Edison Substations,* (2) *Non-Automatic Edison Substations,* (3) *Automatic Railway Substations, and* (4) *Non-Automatic Railway Substations.*

The report includes simplified plans, cross-sections, single line diagrams, cuts of electrical equipment and building exteriors, and tabulations of substation details.

Purpose and Conclusions

The d-c. substation is an extremely important part of the central station power system. While it is probable that the number of Edison systems may decrease rather than increase in the future, the Edison type of substation is, and will be for a number of years, of prime importance in many systems, and it is generally recognized that railway substations will assume increasing importance, particularly in steam railroad electrification zones. For these reasons and as a result of the interest manifested in two previous serial reports on A. C. Substation Design Practice (Publication No. 25-44 and 278-39), this similar report on D. C. Substation Design Practice is presented. These reports, summarizing the latest designs of various companies, enable the designing engineer to keep abreast of new developments and practices making for added reliability and economy, many of which he may find useful in reaching satisfactory solutions to his own problems.

This report presents design data on twenty-seven d-c. substations as follows:

Edison Substations	
Automatic	2
Non-automatic	9
Railway Substations	
Automatic	9
Non-automatic	6
Combined Edison and Railway Substation	
Non-automatic	1

Conversion equipment in these substations includes synchronous converters, motor-generator sets, and mercury-arc rectifiers. The synchronous converter is, as would be expected, the preferred type of apparatus, 49 or 71 per cent of the sixty-nine conversion units reported being of this type. The preference for synchronous converters is slightly more pronounced in railway substations than in Edison substations. Two of the sixty-nine conversion units are mercury-arc rectifiers, one a 3000-kw. unit installed in a 600-volt automatic railway station and the other a 1500-kw. unit installed in a non-automatic station supplying an electrified steam railroad. Since the mercury-arc rectifier is a comparatively recent development in American practice, these figures are not indicative of its true worth, and it seems probable that it will supplant the synchronous converter to a larger extent in the future.

A preference for units of fairly high capacity is indicated, particularly in Edison substations. The capacity of individual machines in the Edison stations varies from 1500 to 4200 kw., with an average of approximately 3000 kw. for synchronous converters, and from 750 to 3000 kw., with an average of about 1600 kw. for motor-generator sets. The largest conversion unit in the railway substations is the 3000-kw. mercury-arc rectifier. The rating of synchronous converters in these stations ranges from 500 to 1500 kw., averaging 1000 kw., while the capacity of motor-generator sets varies from 1000 to 1500 kw., averaging 1250 kw.

Agreement is general on the synchronous motor for driving motor-generator sets in both Edison and railway substations.

The trend toward automatic substations, as indicated by the stations covered in this report is much more marked in the case of railway stations than in Edison stations. Whereas all but two of the twelve substations supplying Edison service are non-automatic, nine of sixteen substations serving railway loads are automatic. It will be noted that automatic control has been applied in these cases to several units of 1500 kw. capacity, and to one rated at 1875 kw., indicating the suitability of automatic equipment for the control of large units.

The necessity for the utmost reliability of service consistent with reasonable investment has a determining influence on the station layouts, particularly in Edison substations. In practically every case two or more incoming lines are provided, and in many cases it has been found necessary to provide duplicate high- and low-voltage buses with adequate sectionalizing facilities. An isolated-phase a-c. structure has been adopted for one Edison substation, and in several of the Edison stations system standby storage batteries, floating on the bus, have been installed. In contrast with this practice, several companies have found it possible to simplify their designs to a large extent, with the elimination of buses, oil circuit breakers, etc.

The limited space available for substation locations in congested downtown urban areas is also reflected in the layouts. Examples are included in the report of four- and five-story substation buildings with basement and sub-basement, and of other buildings of restricted dimensions, irregular in shape. Some companies have overcome this difficulty by installing their equipment in leased space in the basement of office buildings, and several examples of this kind are also included in the report.

Publication No. 289-82. Serial Report, Electrical Apparatus Committee.

SECTION I

AUTOMATIC EDISON SUBSTATIONS

Kansas City Power and Light Co., Kansas City, Mo. Substation "T"

This company is operating five fully automatic d-c. substations, each station equipped with two rotary converters with transformers and the necessary control equipment to make them fully automatic. These ten equipments supply the entire Edison system with power. The equipment of the four of the substations is identical and in the fifth the control is the same as in the other four, but the rotary converters are larger.

The five stations are supplied with power from three cables direct from Northeast Generating Station, and there is one normal and one emergency cable for each machine.

The machines are so arranged that any one of the three cables may be out of service, and all machines will still operate on either their normal or their emergency position, and neither of the other two cables will be overloaded. The ordinary safety devices are provided for the machines, including single-phase starting, a-c. under-voltage, wrong position of brushes, incomplete start, underspeed field failure, wrong polarity, low d-c. voltage when closing on the bus, reverse power, overload on transformer or on rotary converter, hot bearings, d-c. flashover, low water in load limiting resistors, d-c. overload, high d-c. voltage, overspeed, and poor power factor.

On the d-c. side the machines do not trip off from overload, but water-cooled resistors are inserted when the load reaches a certain point. These water-cooled resistors have a capacity much greater than the output of the machine, and cooling water is supplied from the city mains when the temperature reaches a certain point so that they may continue in service indefinitely.

The system of operation used in the automatic equipment consists in bringing on a machine when the voltage on its bus drops to a certain point. The machine starts and comes on the line, and the voltage is then regulated to maintain a certain predetermined value in a selected manhole in the district. The machine operates until the load drops below a certain point, when it is shut down.

These five substations are all located in basements or sub-basements of large down-town buildings, and in every case are located below the street and alley level.

The building in which Substation T is located is a ten-story office building, situated on the southwest corner of the intersection of Tenth and Walnut Streets. The machinery entrance and air intake is located in the sidewalk on the Walnut Street front, and the traffic over the grating is very heavy for a large part of the day. Being below street grade, artificial ventilation is necessary; and as it is the practice of this company to make all equipment fully automatic, it was necessary to provide automatic control for the fans as well as for the louvers. The control for this substation provides the following operation:

Two fans are provided for the substation, one of which is controlled by each of the machines. This control starts the fan when the rotary converter is closed onto the d-c. bus, provided the temperature in the substation is above a certain point. If the temperature is low, the fan motor is not energized until the station warms up. In cold weather, after the fan starts, to prevent one end of the substation being very cold while the other end is still warm, a recirculating duct, which connects the exhaust with the intake, was built along the ceiling near one side.

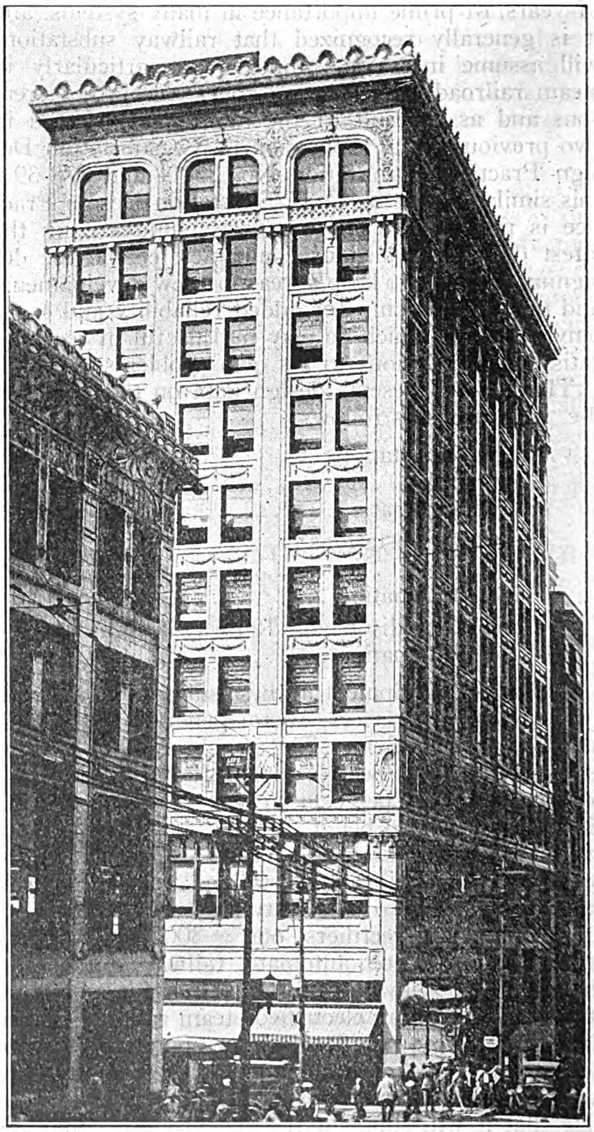

FIG. 1—EXTERIOR VIEW OF OFFICE BUILDING IN WHICH SUBSTATION "T" IS LOCATED.

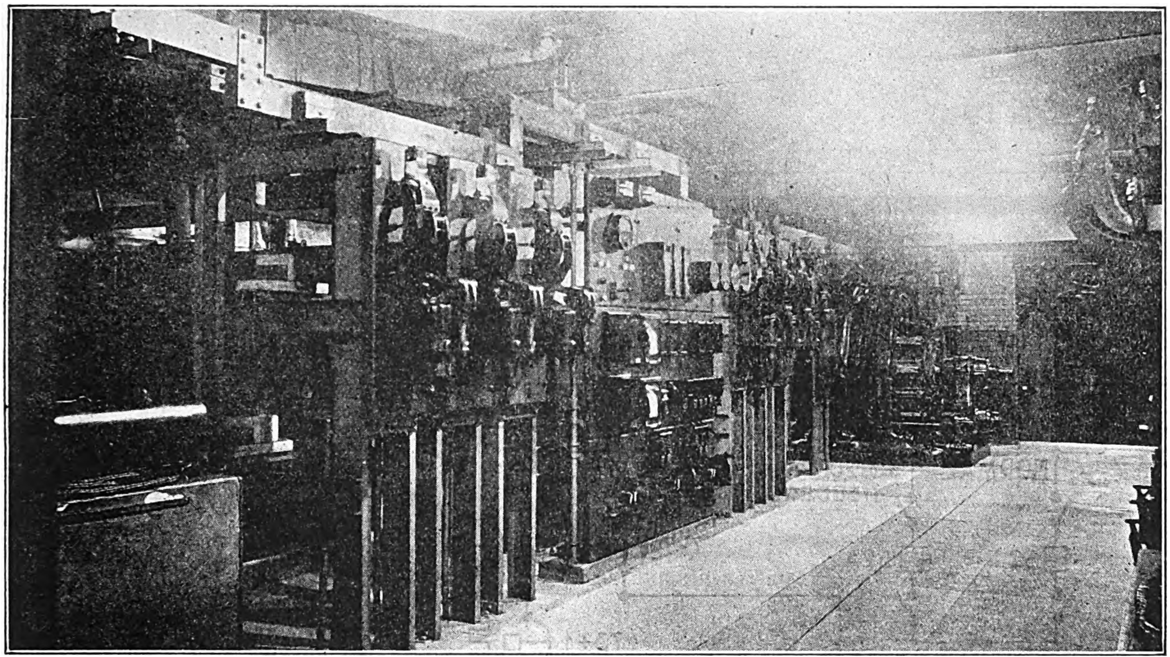

FIG. 2—GENERAL INTERIOR, SUBSTATION "T."

This recirculating duct is closed by automatic louvers which open sufficiently to keep the temperature of the substation nearly constant. Steam heating equipment is also provided to prevent the temperature going too low when the station is down. An automatic valve is provided to turn on the steam when it is needed.

The air intake being located in the sidewalk, a very large amount of dirt, much of it very fine, is taken in with the cooling air. To prevent this dirt and dust entering the equipment, dry or viscous type air filters are provided between the intake and the substation. These filters are made up in unit cells and effectively prevent all dirt and dust from getting into the substation.

In order to forestall complaints in summer due to discharging hot air where it could enter other buildings, a duct was installed, extended from the fan exhausts to the roof of the building, a distance of 138 ft.

Union Gas & Electric Company, Cincinnati, Ohio—Jackson Street Substation*

General Description

This substation is located in the downtown section of Cincinnati, on Jackson Street between Twelfth and Thirteenth Streets. The building itself is constructed of red wire-cut brick and contains one story and a basement. In order to cut down noise of operation and fire hazard, the station has no windows. This substation is entirely automatic in operation.

In the basement are located the ventilating filters, the switch positions, the starting reactors, the switchboard, and the 125-volt control battery. The first floor contains the 1875-kw. motor-generator set with enough additional space for a second unit. The motor-generator set has a direct connected exciter on the shaft of the machine. In the roof of the building are monitor air outlets.

Ventilating System

The ventilating system of the Jackson Street Substation is of the natural draft type. The air enters the substation through an airshaft and air filters, located in the basement wall, and passes upward through the substation, around the motor-generator set, and thence out through the monitor air outlets in the roof.

The motor of the unit has inclosures on each end and fans on the rotor. The generator of the unit has inclosure on rear end with commutator end open. Fans are provided on the rear end of the generator rotor only. When the motor-generator set is in service it is possible to move approximately 19,600 cu. ft. of air per minute with this system.

A system of baffling has been installed in the substation to reduce the amount of noise going out through air inlet and outlet openings. The baffles consist of "V" shaped pieces of sheet steel covered on all sides with ½ in. of hair felt. These are in a series slightly overlapping one another. They are installed in the discharge and inlet openings. It is estimated that the installation of the baffles has reduced the noise getting out of the substation to 25 per cent of what it was before their installation.

Relaying

The relaying at this substation is of the standard type for automatic substations. The equipment is fully protected against all types of faults, as shown by the following:

Motor-Generator Set:

1. Overload and ground relays.
2. Thermostat overload relays.
3. Under-voltage relays.
4. Bearing temperature relays.
5. Speed limit relays.
6. Flash relays (connected between base plate and ground).
7. Reverse phase relays.

Automatic Motor-Generator Set Control

The 1875-kw. automatic motor-generator set ha fully automatic control. The machine is used to supply direct current to the Edison system of the Unio Gas & Electric Co. in Cincinnati, Ohio. The motor of the machine is wound for 13,200 volts, 3-phase, 60-cycle alternating current. The generator delivers direct current at 230 to 280 volts, two-wire.

The machine is supplied by two incoming 13,200-volt lines, one designated at the preferential source and the second as the emergency source. The emergency source is kept energized at all times. In case of failure of the preferential source the motor-generator circuit is automatically transferred to the emergency source.

The machine can be arranged to start by energizing the supply feeder at a nearby a-c. substation which has an attendant, or by use of a pilot wire.

Starting the motor-generator is accomplished by a time switch which closes the 13,200-volt line oil circuit breaker. The set starts through series reactors, and when it comes up to speed the reactors are short circuited by another oil circuit breaker, and the field is automatically applied to the motor. In case of a momentary a-c. system voltage disturbance that would cause the motor to pull out of step, the field is automatically removed and reinstalled after recovery of the a-c. supply to normal.

The load on the d-c. generator is controlled by both current and voltage relays. The current relay permits loading the machine on a temperature basis. The voltage relay limits machine voltage and, in turn, the load during light-load periods.

In the case of sudden overloads due to adjacent substations dropping out during full load or in the case of energizing a dead Edison system, current limitation is accomplished by a differential field winding. This winding is normally short-circuited by a breaker which trips on application of sudden overloads of more than two and one-half times rating.

NON-AUTOMATIC EDISON SUBSTATIONS

The Cleveland Electric Illuminating Company, Cleveland, Ohio—Bolivar Substation

This substation is the one most recently constructed in the d-c. district of Cleveland. Three 13,000-ampere booster type rotaries are in service, and space is provided for a total of five machines of this rating. Incoming supply is from 11,000-volt underground cables. A storage battery of approximately 10,000 ampere-hr. capacity (one-hour rating) is located on an upper floor. The front portion of the substation building is occupied by offices.

Switching is semi-automatic. A single operation by the attendant starts up a rotary and puts it on the line at light load. Adjustments of load, voltage and power factor are by manual control only. Load limiting resistors are cut in automatically at or above 50 per cent overload. When the station reaches its ultimate development it should be able to pick up a dead system without the aid of the storage batteries.

FIG. 19—SECTION, BOLIVAR SUBSTATION.

Commonwealth Edison Company, Chicago, Ill.—Burnham Bldg. Substation

This substation is located in space leased in the sub-basement of an office building. It receives 12,000-volt, 60-cycle, 3-phase energy from the company's generating stations over three-conductor underground cables, two G. E. 13,000-ampere, 225/275-volt synchronous booster converters are used to convert this energy to direct current for use on the Edison 3-wire system, and for direct feeders to surrounding buildings. The substation also contains a 10,500 ampere-hr. battery, 1-hour rate, which floats on the system.

The high-tension bus structure is of the horizontal isolated-phase type. Oil circuit breakers are interlocked electrically and mechanically. Relays in 12,000-volt tie lines to other substations are the balanced differential type with a non-directional induction type relay on one end. Relays on the a-c. side of converters are inverse-time overload. Provision is made for the installation of a fault-bus which kills any section of the bus should there be a flow of current to ground over any of the normally grounded parts of breakers, disconnecting switches, and instrument and main transformers.

The synchronous converters are of the booster type. The main transformers are air-blast cooled and are mounted on the converter bases, being what is termed the consolidated type. Air is taken from an opening in the sidewalk through air filters. Blowers force the air into a duct under the floor which opens into each synchronous converter and has openings also into the substation space. The transformers have separate blowers because they require higher air pressure. The heated air from converters and transformers is exhausted through a duct on the ceiling which terminates in the alley. The synchronous converters are normally started on the high-tension side by means of two electrically and mechanically interlocked non-automatic oil circuit breakers using the star-delta method. Direct-current starting equipment is also provided.

The direct-current energy goes through remote controlled air-circuit breakers, mounted separately, and then to the armature knife switches on the feeder switchboard.

The d-c. circuit breakers are equipped with what is termed "service restoring equipment," which consists of a load-limiting resistor and an auxiliary air circuit breaker connected in parallel with the main positive air circuit breaker. In cases of a-c. system disturbances which cause momentary dips in the 12,000-volt pressure, the converter will invert. When this happens, a d-c. reverse current relay functions to open the main positive air circuit breaker, thereby inserting the load-limiting resistance and auxiliary air circuit breaker in the positive lead and at the same time opening the neutral circuit breaker. This limits the inverted load to the commutating ability of the converter. If the 12,000-volt pressure is restored within the limits of a thermal relay on the load-limiting resistor, the reverse current relay functions to close the main positive breaker, connecting the converter directly to the bus. If, however, the 12,000-volt pressure remains down beyond the thermal limit of the resistor, a thermal relay functions, opening the negative and auxiliary air circuit breakers and the converter a-c. main and running oil circuit breakers. This leaves the equipment ready to be restarted in the usual manner when the 12,000-volt voltage is restored to normal.

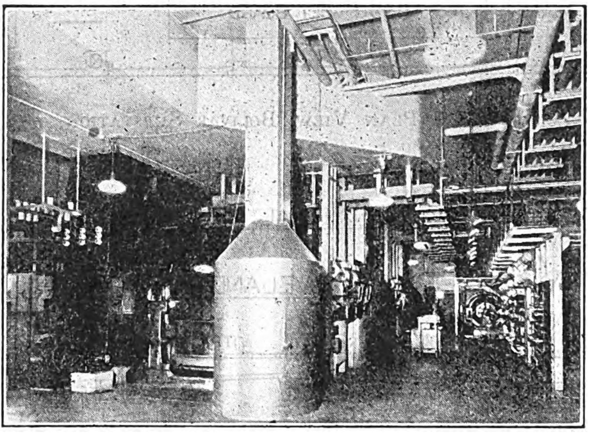

FIG. 20—INTERIOR VIEW SHOWING CONSOLIDATED TYPE SYNCHRONOUS CONVERTER, BURNHAM BLDG. SUBSTATION.

This feeder switchboard has the positive switches on one side and the negative on the other. Switchboard steel is insulated from ground. The feeders are run from this switchboard to the duct outlets on racks which keep each cable separate, and additional protection is provided by fire-proofing each cable with hemp rope and a mixture of sand, cement and fireclay.

The control switchboard has all the necessary control for the high-tension bus, the converters, the booster which is used for charging the battery, and the battery end-cell switch control. A separate operating battery is provided with a carbon pile rheostat for charging from the d-c. bus.

The machinery entrance is through the sidewalk, removable slabs being provided over the shaft through which the machinery is lowered to the substation floor.

The Detroit Edison Company, Detroit, Mich.—Charlotte Substation

This substation is one of the newest Edison System substations now in operation on the Detroit Edison Company's system. The present installation consists of three differentially wound, 2400-kw., motor-generator sets, with a 600-kw., 3-unit balancer. Provision is made for the installation of two 4800-kw., 3-unit machines, making an ultimate station capacity of 16,800 kw. Each machine is fed directly by a 4800-volt tie line, with provision for jumpering to a spare line in case of the failure of one of the lines in use.

Main and auxiliary d-c. buses are provided, with double-throw knife switches to connect machines and feeders to either bus. In the feeder rooms, positive and negative buses are on opposite sides of the room. Provision is made for the future installation of feeder circuit breakers in place of the double-throw knife switches now in use. Ammeters are installed on both positive and negative feeders.

Use of a 3-unit balancer set provides some reserve converting capacity as well as balancing service. The balancer is fed through its own tie line and can be jumpered to the spare line in the same way as the motor-generators.

Cooling air is washed and blown through the machines and discharged into the machine room, whence it is removed through gratings in the ceiling by exhaust fans. The air can be recirculated if it is deemed advisable. Machines are partially enclosed. The air outlet on the motors is at the top; and on the generators the air passes over the commutator as it leaves the machine.

The differential winding on the machines acts to limit the load so that there is no other overload protection necessary on the d-c. end of the units.

The substation is of fireproof construction throughout, with the feeder rooms isolated from the remainder of the bus room in the basement. Hand Pyrene fire extinguishers are provided for use in case of insulation fires in the machines, etc.

FIG. 33—SECTIONS, CHARLOTTE SUBSTATION.

Edison Electric Illuminating Co. of Boston, Boston, Mass.—Carver St. Substation

The general arrangement of apparatus in the Boston Edison converting stations follows the idea represented by the cross sectional view of the Carver Street substation, viz.: duct lines in basement; machines on the first floor, corresponding approximately with the street level; a-c. switching and bus compartments next, and the battery rooms above the a-c. compartments. In case the lot area will not allow of the operating room being on the first floor, as is quite generally the case, there is an additional floor for the switchboards above the machine room and the isolated-polarity d-c. breaker structures are installed above the duct lines, increased head room being allowed in the basement.

The arrangement of ducts for the d-c. feeders is in the form of tiers or stacks, each of which is two ducts wide. Each stack of ducts is carried the entire length of the building, when each end has a street frontage, and in this way a feeder may leave its circuit breaker in either direction, according to which street routing will work out best for the distribution system. The duct stacks are continuous from street vault to street vault, and when a feeder is to be installed, the stack is broken into at the duct to be occupied, just below the breaker assigned to the new feeder. From this point to the bus the polarities are kept separate, leaving the "D sector" leaded cable by a Y-joint, the positive and negative cables are each carried to their own circuit breakers.

The rotary converter, its transformer and the a-c. starting equipment are all grouped on the machine floor, and below in the basement are the machine breakers, the field rheostats and the transformer blowers, all grouped near the machine to which they are related. The machines are cut into the bus so as to distribute their loads with a minimum of copper, each machine being grouped with its approximate proportion of feeders.

Both a-c. main and transfer buses and the high and low d-c. buses are sectionalized at intervals and the a-c. buses are ringed. Copper runs of high density current are consistently short; the battery runs, considered more or less emergency when called upon to carry full density, are the exception.

An auxiliary power bus is carried near the d-c. switchboard, and sometimes on entirely separate panels, for supplying station light and power and the converter field energy. The sources of supply for this bus are carefully chosen, with a view to minimum interruption. All pilot and indicating lamps are supplied from the auxiliary power board but from a separate bus fed from the control battery.

On the benchboard is a pressure wheel, whereby a rotating arm connects to the voltmeter whatever d-c. feeder is desired by revolving the pointer to the required number located on one of the segments of the wheel. To read the voltage of each feeder in this manner a pilot wire is brought from the distribution center of the feeder within its sheath and, at the station end, carried together with other pressure wires to a pressure wire fuse board, thence to the pressure wheel. Separate ducts for the pressure leads are provided within the station.

On each floor, and usually in a number of places, are located fault testing stations for lines, feeders or apparatus. Phasing and polarity testing stations and testing potential for laboratory work are located wherever conditions require them.

The station is lighted throughout by direct illumination reflected with RLM domes, the size of units and mounting heights being varied to give proper intensities.

In the a-c. compartments are separation walls of expanded metal lath and plaster between line and line or line and machine, and between compartments are 6-in. concrete walls. The only phase separation outside of air spacing is at disconnect switches, fuses, bus and in the oil circuit breaker. At disconnecting switches and fuses, asbestos ebony barriers are used, and the bus itself is carried in isolated concrete construction. Transversely with the cells, at intervals of every half dozen groups, are fire walls of 4 or 6-in. concrete; the bus is carried through this in porcelain tubes, and all cable is similarly carried through the longitudinal walls.

Both a-c. and d-c. starting of converters are utilized at many Boston Edison substations, although a-c. is becoming standard. The star-delta starting is quicker and more satisfactory; brush lifting control is interlocked with the starting breaker to insure the up position when starting, and interlocked with d-c. breakers to insure the down position when converting. Starting and running breakers are interlocked and timed by a time-delay relay to insure smooth starting. An additional device is employed where both a-c. and d-c. starting are available on one machine to allow d-c. starting and closing of running breaker without the routine of operating the starting breaker first.

Generally, all converting stations operate on 13,-800-volt lines radiating direct from the generating station, the lines being equipped at both ends with overload relays. Lines looped through substations have overload protection on leaving and reverse energy protection on incoming ends.

Fire protection is thoroughly covered by systematic mounting of fire extinguishers on distinctively painted metal backgrounds, sand pails with fiber scoops, and a very thorough isolation of portions of the equipment. The stairways are entirely inclosed in brick walls, all doors swing out of apparatus rooms, and there are exits to the street and roof at both the front and the rear of the substation.

FIG. 40—SECTION, CARVER ST. SUBSTATION.

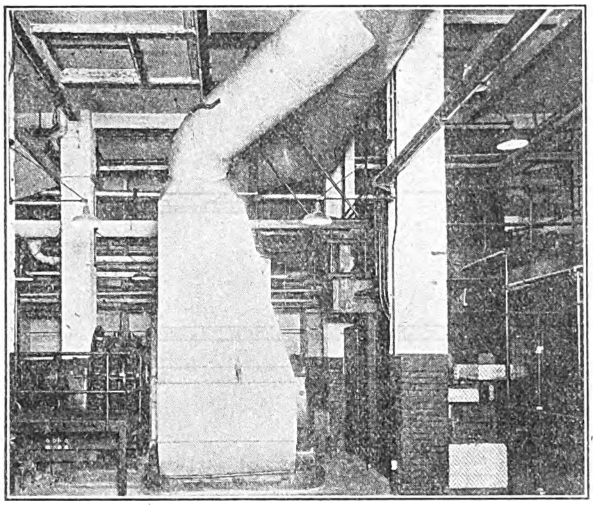

FIG. 41—3900-Kw. Synchronous Converter Installation—Stephenson Bldg. Substation.

The Milwaukee Electric Railway & Light Co., Milwaukee, Wis.—Stephenson Building Substation

This substation is located in the basement of one of the downtown office buildings and serves a portion of the 125/250-volt d-c. Edison system. The station has space for an ultimate capacity of four rotary converters, but only two are installed at present, one 2775-kw., manually operated machine, and one 3900-kw., semi-automatic converter with water-cooled load-limiting resistor. The latter machine is shown on accompanying drawings and photographs.

The 4200-kv-a. transformer is air cooled, and the rotary converter is kept cool by means of a sheet iron inclosure leading to a stack running to the roof of the building, which carries off the hot air from the machine before it can recirculate about the room. Cool air is supplied to the machine and transformer through openings in the sidewalk.

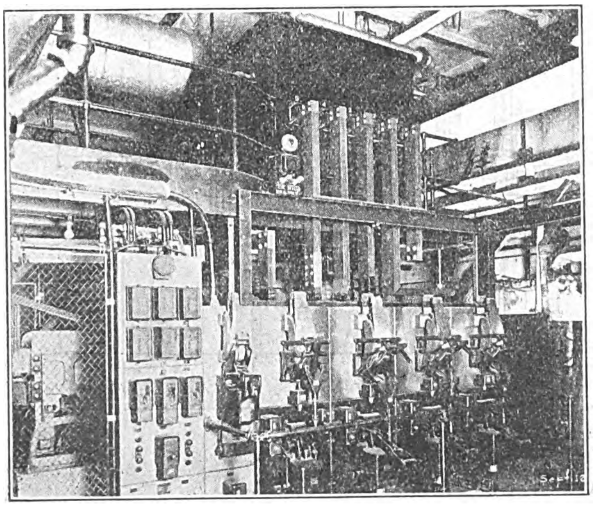

FIG. 42—Load Limiting Resistor Installation, Stephenson Bldg. Substation.

Water-cooled resistors are installed in the negative lead and limit the load on the machine to 150 per cent of its capacity. This resistance is cut in and out of the circuit automatically by means of circuit breakers.

FIG. 45—Section, Stephenson Bldg. Substation.

New Orleans Public Service, Inc., New Orleans, La.—Dryades Substation

This substation, located in the commercial district, receives its power from the main generating station through six 6600-volt underground feeders. This power is delivered to the following loads:

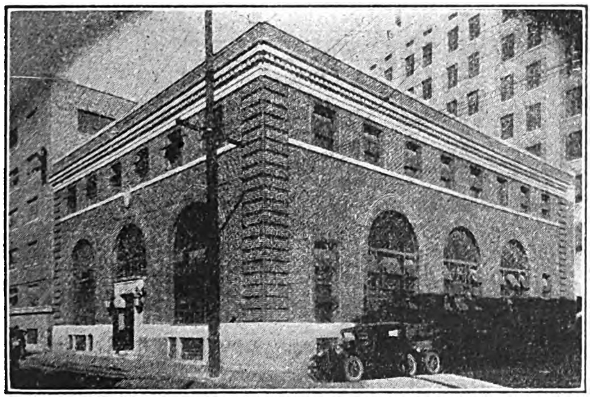

FIG. 46—Exterior, Dryades Substation.

(a) Edison 220-volt d-c. system.
(b) 600-volt railway system.
(c) 4000-volt commercial feeders.
(d) Mercury-arc rectifiers and Whiteway circuits for street lighting.

The conversion apparatus for the Edison load consists of two motor-generator sets supplied directly from the 6600-volt bus and one 6-phase rotary converter connected through transformers to the 6600-volt bus. These machines feed into the Edison 220-volt, 3-wire system through thirty-five d-c. feeders.

Two 6-phase rotary converters connected through transformers to the 6600-volt bus feed through seventeen feeders into the 600-volt, d-c. railway system.

From the 6600-volt bus two banks of transformers supply a 4000-volt bus, from which power is delivered to 4000-volt feeders for local distribution, and three Whiteway transformers and circuits for street lighting.

Power is supplied to twelve street lighting circuits from mercury-arc rectifiers connected to the 6600-volt bus.

All Edison feeders are entirely underground. All feeders are brought into the station underground.

FIG. 50—SECTION, DRYADES SUBSTATION.

The New York Edison Company, New York, N. Y. —East 32nd Street Substation

This substation typifies the construction and layout necessary in a substation built on small city lots, and yet giving ample street frontage for outlet of feeders and ducts.

The substation is built on three 25-ft. lots in the form of a "T," and has frontage on three streets. Each section of the "T" will ultimately be equipped with two 4200-kw. converters, the output of the converters leaving the station through feeders in the same section in which the converters are installed. The control room is located at the midpoint of the "T" and is remote from the rest of the apparatus.

Successful means were employed throughout the erection of the substation for the elimination of vibration and noise. Cork insulation was used between the substation and adjacent buildings. The rotary converter foundations are entirely separate from the main building, and the converters and transformers are inclosed in sheet steel housings. The air intake

and outlet ducts are padded, and a special system of padded louvres is effectively used in the fresh air inlet.

The incoming high-tension feeders and the converter transformers have only overload relay protection. The direct-current end of the machines has overspeed protection but no overload or reverse-power relays.

The electrically operated d-c. feeder circuit breakers are located near the street entrance of the feeders, thereby eliminating all station runs for both feeders and converters. They are arranged to protect from cable faults only. This is accomplished by connecting their trip coils through a control wire in the feeder cable to the trip coils of the junction box breakers. A cable fault thereby simultaneously opens the feeder at both ends, and notifies the operator through an annunciator system and horn.

The New York Edison Co., New York, N. Y.—Madison Avenue Substation

This substation is installed in the basement of a large office building in a midtown business district. Due to a very low ceiling, special equipment, consisting of a large capacity sidewalk lift and a special cradle was necessary for handling the substation apparatus.

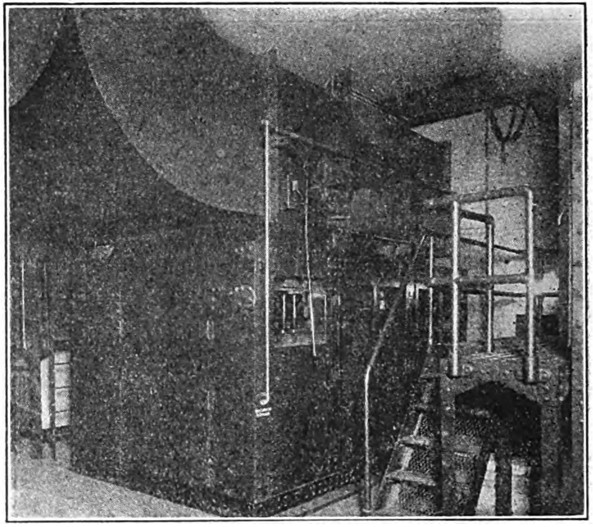

FIG. 60—4750-Kv-a. Transformer Installation, Madison Ave. Substation.

Each air blast transformer is mounted on its side, and supplies two 2100-kw. converters.

The elimination of noise and vibration being essential, the substation floor and converter foundations are padded with cork and the inlet air duct, entering into a courtyard, is equipped with soundproofing louvres. All air from the rotary converter housings and transformers discharges into a hung ceiling which exhausts into a chimney running to the top of the building.

The transformer secondaries consist of two 6-phase diametrical windings, one for each rotary converter. Only three synchronizing breakers located beneath the transformers are required for each rotary converter as the midpoint of the transformer windings is not connected. A fourth breaker is installed to ground the machine through a low resistance when it is desired to work on the converter when the transformer is excited.

The high tension and d-c. feeder equipments are the same as for East Thirty-second Street Substation except that the d-c. feeder circuit breakers are mounted above knife switches in the switchboard room.

FIG. 63—PLAN, MADISON AVE. SUBSTATION.

The Northern States Power Company, Minneapolis, Minn.—Sixth Street Substation

This substation operates in parallel with another substation of similar design, and a 1200-kw. automatic substation. These three substations serve a d-c. network in the loop district of Minneapolis. The following description deals with Sixth Street Substation:

Standby Battery

This substation is equipped with a 150-cell Exide battery of 8184 ampere-hr. capacity at the 8-hr. discharge rate or 14,652 amperes for 10 minutes. This battery is floated across the d-c. bus at all times. Two batteries of the same size are floated on the d-c. bus at another substation. Remote controlled, electrically operated end-cell switches are provided. This battery is charged from the d-c. bus by means of a booster motor-generator set. Suitable cables and switches are provided to make it possible to connect a booster generator to any cell or group of cells for special charging. Special charging can be carried on while the battery is tied to the d-c. bus.

D-C. Buses

Two separate 3-wire, 250-volt d-c. buses are provided, and the d-c. switching equipment is so arranged that any feeder or generator can be connected to either or both of the d-c. buses. One of these buses, called the "high" bus, is operated at about 8 volts higher than the other bus, which is called the "low" bus. Those feeders supplying the more remote parts of the d-c. network are connected to the "high" bus and the shorter feeders are connected to the "low" bus. This double bus system permits practically uniform voltage in all parts of the network and divides the load among the various feeders to better advantage.

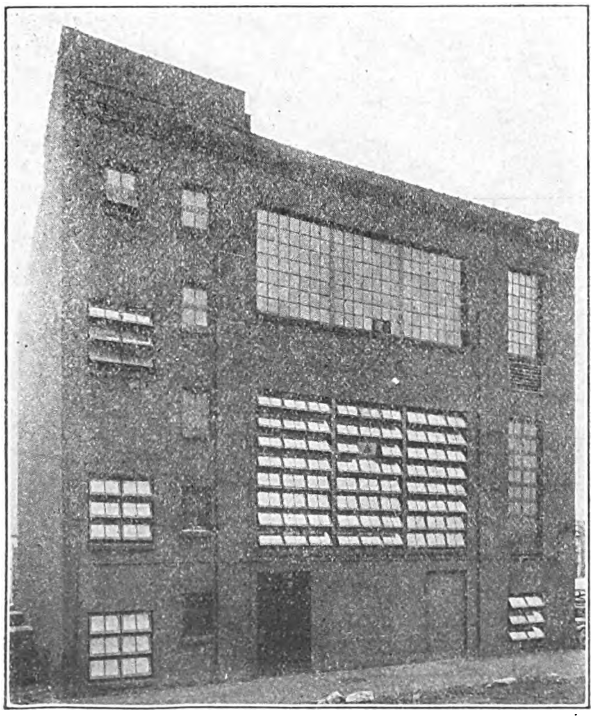

FIG. 64—EXTERIOR, SIXTH ST. SUBSTATION.

Sectionalization of D-C. Network

The d-c. network is segregated into three independent zones for the purpose of giving greater flexibility in picking up the d-c. load in case of an interruption. Each substation serves feeders of all three zones, and the substation d-c. buses serve as the only ties between these zones. These zones are known as the black zone, the blue zone and the white zone. The handle of every feeder switch in each substation is enamelled black, light blue or white, to denote which zone that feeder serves. In case of an interruption the zones are separated by means of feeder switches. All feeder switches for one zone are closed in on one of the buses which is temporarily left dead. This bus is then tied to a second bus which is live. The feeders are then all transferred to the second bus, after which the buses are separated, leaving the first bus dead and available for picking up another zone. The above-described procedure is repeated until all three zones have been picked up.

Control Bus

All oil circuit breakers, all main generator d-c. breakers, and all field rheostats for the motor-generator sets are electrically operated. The 125-volt, d-c. supply for these controls and for the indicating lights is supplied by a 60-cell control battery which is constantly floated on a small battery-charging motor-generator set. Normally the motor-generator carries the control load, and the battery remains fully charged. Between the generator and the control battery is an automatic circuit breaker which will trip on the occurrence of reverse current, overload or under-voltage. The motor is protected for overload and under-voltage. In case of interruption affecting the motor-generator set, the battery serves the controls. The battery is protected by a heavy fuse and the various controls are supplied through a number of fused branch circuits. Pilot lights are connected to each branch circuit to indicate the condition of the fuses. The control bus is operated ungrounded and is equipped with ground detector lamps.

Starting of Machine

In normal operation the motor-generator sets are started from the d-c. end by means of step switches and resistors. During the starting period the field of the d-c. machine is supplied from the main d-c. bus. After the synchronous motor has been synchronized in on the a-c. bus, the field of the d-c. generator is transferred to self-excitation.

The motor-generator sets are provided with compensators for emergency a-c. starting in case of the d-c. bus being dead.

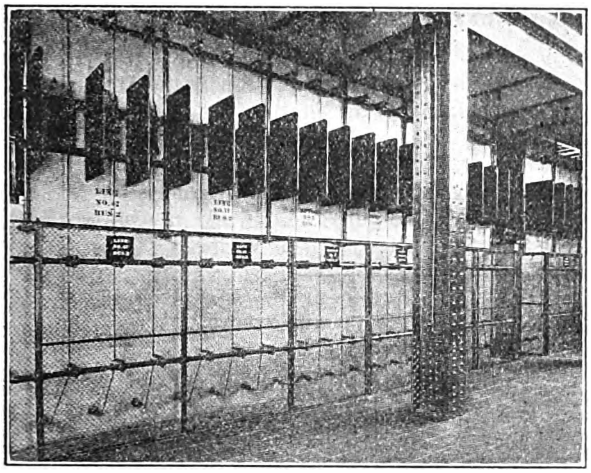

FIG. 65—13.2-Kv. Disconnecting Switches Between Oil Circuit Breakers and Bus, Sixth St. Substation.

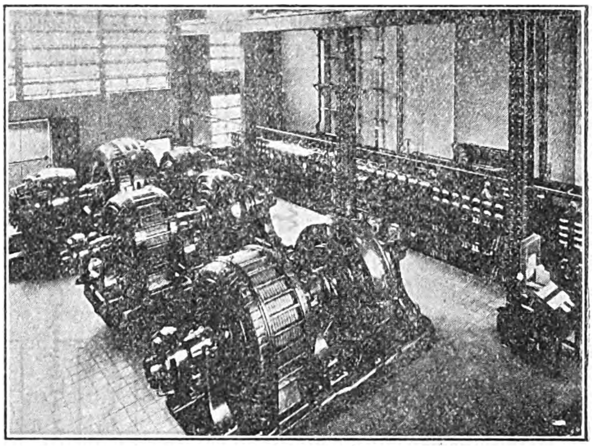

FIG. 66—Machine Room, Sixth St. Substation.

Relays and Protection

Each pair of incoming feeders has balanced protection. With this protection scheme a line will trip out only when there is an unbalance in current between the individual lines of a pair. Then the more heavily loaded line will trip, leaving the other line of the pair in service with straight overload protection.

The synchronous motors are provided with straight overload protection only.

The d-c. generator circuit breakers trip only on the occurrence of a reverse current.

Fire Protection

Fire-extinguishing devices, including Pyrene guns, Phister one-gallon extinguishers, sand pails, and soda and acid extinguishers are located at various points about the substation so that the nearest one is never more than a few feet away. Near each soda and acid extinguisher is a large red sign which cautions against using the extinguisher on live apparatus.

Safety

Wherever high-voltage conductors are not sufficiently protected by the concrete cell structures, wire netting barriers are provided.

A removable wooden bar is placed in front of each set of three cell doors on the FH-203 oil circuit breakers to prevent the mistake of opening a cell of a switch adjacent to a switch which is to be inspected. In addition, the concrete cell wall between each switch and the adjacent switch is painted red so as to clearly mark the limits of each set of three cells.

Interlocks

An electrical interlock is provided which trips the neutral breaker if either the positive or negative breaker is opened. Interlocks are provided to close the neutral breaker when the positive breaker is closed, and to prevent the positive breaker from closing when the negative breaker is open. The interlocking scheme also prevents closing the positive high bus breaker if only the negative low bus breaker has been closed and closing the positive low bus breaker if only the negative high bus breaker has been closed.

FIG. 70—Section, Sixth St. Substation.

Union Gas and Electric Company, Cincinnati, Ohio—Baker Alley Substation

The general practice in Cincinnati is to locate large manually operated substations at approximate load centers with small automatic substations spaced between. This practice is followed out in both the a-c. and the d-c. systems. Of the substations supplying the Edison system, the Baker Alley Substation is the best example of modern design for the large manually operated substations. The Jackson Street Substation is also a very good example of a small automatic d-c. substation.

Baker Alley

This substation of the Union Gas & Electric Company is located in the downtown section of Cincinnati. The building is constructed of red wire-cut brick and contains five floors, a basement and a sub-basement. This substation building contains no windows except those in the monitor above the fifth floor. This feature reduces the fire hazard to the substation from adjoining buildings and prevents undesirable noises from the rotating equipment. The equipment in the building is located as follows:

Sub-basement

150-cell, 9300-ampere-hr. stand-by storage battery.
60-cell, 120-ampere-hr. control battery.

Basement

D-c. buses, breakers and feeders. Control and ventilating equipment for rotating machinery and end cell switches for the Edison storage battery. Also starting and running breakers for rotary converters and motor-generator sets.

First Floor

Two 3700-kw. rotary converters with their two 4000-kv-a., 13,200/192-volt transformer banks.
Two 1500-kw. motor-generator sets. 13,200-volt a-c. 250-volts d-c.
Two 6000-kv-a., 13,200/4325-volt transformer banks.
These transformers supply a-c. distribution.
Eight 72-kw. constant-current transformers for street lighting.
One 30-ton crane for handling equipment.

Second Floor

Control room consisting of 27 control panels and 8 relay panels.
Motor-generator sets for charging control battery.

Third Floor

4325-volt apparatus room containing positions for 8 regulated feeders and 2 non-regulated feeders.

Fourth Floor

13,200-volt bus and breaker room equipped for 13 circuits all having dual switching. The main bus is separated into two parts. Reactor structures have been built to equip all 13,200-volt positions with current-limiting reactors.

Fifth Floor

Two intake air fans.
Intake air filter (dry type).
Four exhaust fans.

Ventilation

The first floor is constructed so that the space occupied by the rotating equipment, which is slightly more than one-half the width of the building, is three floors high.

The second floor is a mezzanine to the machine room with a glass partition on the side overlooking the machines. This is the control room for the station.

The ventilating system of this substation is one of the unique features in the design. All the air for ventilation is taken in at the roof through dry air filters, and after going down through the building is discharged again at the roof.

The air is admitted through the roof monitor to an intake chamber located on the fifth floor. It then passes through the air filters, which comprise one-half of the walls of the intake chamber, into a second chamber. From this chamber it is drawn through two 50-h.p. induced draft fans to an air well on each end of the building. The air wells extend from the fifth floor to the first basement level, where the forced draft fans are located. These air wells are also used as stairways, and iron grating stairs are used throughout to get greater area. The circulation of the air down these two wells is aided by two 30-h.p. forced draft fans located in the basement which force air through the rotary converters and thence through ducts along the wall to the exhaust room located on the fifth floor. Both rotary converters are totally inclosed. Two 20-h.p. forced draft fans ventilate the rotary converter transformers which discharge the air directly into the machine room. The power transformer banks are cooled by means of two 30-h.p. forced draft fans also located in the basement. The air is forced through these banks and thence through ducts to the roof.

Ventilation for the machine room is furnished by two 25-h.p. exhaust fans located on the fifth floor with intake openings in the ceiling of the machine room. Auxiliary openings in the ducts for these fans are located in the fourth floor switch room, the discharge being taken through the fifth floor roof to the outside.

Ventilation of the second floor control room and the third floor regulator room is accomplished by means of louvres into the north and south air wells.

The battery room in the basement requires special ventilation due to the acid fumes from the battery. Two 15-h.p. exhaust fans located on the fifth floor draw the exhausted air from the battery room through acid eliminators located at the intake of the ducts. Fresh air is drawn into the battery room through special ducts directly from the fifth floor. These exhaust fans discharge directly through the roof.

The ventilating system when in full operation moves approximately 125,000 cu. ft. of air per minute throughout the station.

Feeders

The present number of feeders consists of four incoming and one outgoing 13,200-volt a-c., four outgoing (three regulated and one non-regulated), 4325-volt a-c., and 28 outgoing 250-volt d-c. feeders. The ultimate capacity of this substation is four incoming and three outgoing, 13,200-volt a-c., ten outgoing (eight regulated and two non-regulated), 4325-volt a-c. and 60 outgoing 250-volt d-c. feeders. All these feeders leave or enter the substation underground. The substation is also laid out to supply eight 70-kw., 6.6-ampere constant-current street lighting circuits.

Relay Equipment

Incoming Lines—Balanced directional.

Outgoing Lines a-c.—Overload.

Rotary converters and motor-generator sets.

A-c. overload and ground.

Bearing temperature.

Overspeed.

Flash relay (frame of machines connected to ground through a relay).

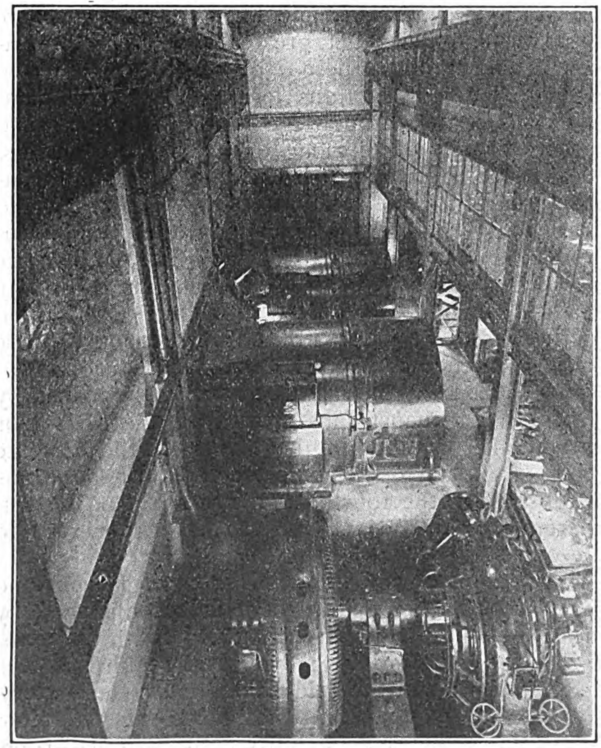

FIG. 71—MACHINE ROOM, BAKER ALLEY SUBSTATION.

D-c. Feeders

Breakdown or burnout on d-c. cables energizes a pilot wire which in turn energizes a tripping coil on the feeder breaker.

Rotary Converter and Motor-Generator Control

These machines have a system of control which might be termed "semi-automatic." To start a machine, the operator closes the main line a-c. switch and the starting sequence from then on is automatic up to the last d-c. breaker to parallel the machine with the d-c. system. The operator closes this d-c. breaker.

The rotary converters in Baker Alley Substation have a special feature on the d-c. end which was developed in Cincinnati and which has given an excellent account of itself.

The a-c. supply system to Baker Alley Substation is subjected to severe voltage drops that take place when short circuits or other disturbances occur on other parts of the system. The rotary converters operate on the station bus on which stand-by batteries float. When there is a depression in voltage the rotary converters tend to reverse and clear themselves from the d-c. bus. After the disturbance the machine must then be paralleled with the d-c. bus by the operator. This requires from one to two minutes, depending on conditions.

The special features developed here consist of tying the machine to the d-c. buses by single-pole breakers; one of the breakers connects the machine direct and the other short-circuits a resistance. When an a-c. disturbance takes place, the breaker short-circuiting the resistance opens on reverse current. This leaves the machine connected to the d-c. system through the resistance. Upon recovery of the a-c. voltage, the breaker again closes automatically across the resistance and normal operation is resumed. The resistance is protected by thermal relays.

SECTION III

AUTOMATIC RAILWAY SUBSTATIONS

Cleveland Railway Co., Cleveland, Ohio—Standard Automatic Substation

The power conversion system at the present time consists of five manually operated substations having a total installed capacity of 31,500 kw. and ten automatic substations with an aggregate capacity of 24,000 kw. The company is definitely committed to the utilization of the automatic substation to the extent that the present manually operated plants are either to be supplemented by automatically operated plants or the present plants automatized. In view of the fact that the entire system will be automatic in the near future, the data herein submitted are limited to the automatic type of substation.

Principal among the unusual features found in these substations are the following:

1. Method of control of outgoing d-c. feeders.
2. Electro-pneumatic contactors.
3. Sheet steel high-tension bus and cell compartments.
4. Remote supervisory control including remote metering.
5. Utilization of the one size converter.
6. Location of current-limiting resistance.

1. Method of Control of Outgoing d-c. Feeders

All substations are equipped with main and auxiliary d-c. positive buses. The d-c. feeders are normally connected through contactors to the main bus, receiving their power from the converters located in each particular substation. In the event of short circuit on a feeder by reason of grounded trolleys, the feeder is automatically transferred to the auxiliary bus without delay. In this position, it receives energy from the main bus through a current-limiting resistance and from additional feeders fed from other stations which may be transferred by the load-dispatcher to the auxiliary bus. When the short circuit has been removed by the burning-off process, the feeder is automatically connected to the main bus again by being retransferred.

2. Electro-pneumatic Contactors

To insure supply of energy to trolleys and further to enable the load-dispatcher to exercise control of d-c. feeders and the system under all conditions, electrically controlled, pneumatically operated locomotive-type contactors have been utilized for all feeders. This type of contactor has also been used for all heavy-current d-c. circuits of the converters.

3. Sheet Steel High Tension Bus and Cell Compartments

To economize space, facilitate erection and obtain lower initial costs, sheet steel bus compartments, switch compartments, and cell structures have been used throughout.

4. Remote Supervisory Control Including Remote Metering

All automatic substations, while designed to operate fully automatically, have superimposed upon their control a complete system of remote supervisory control for the operation of converters and control of outgoing d-c. feeders. This enables securing the most efficient operation from the converters and insures the very highest degree of continuity of service from the substations.

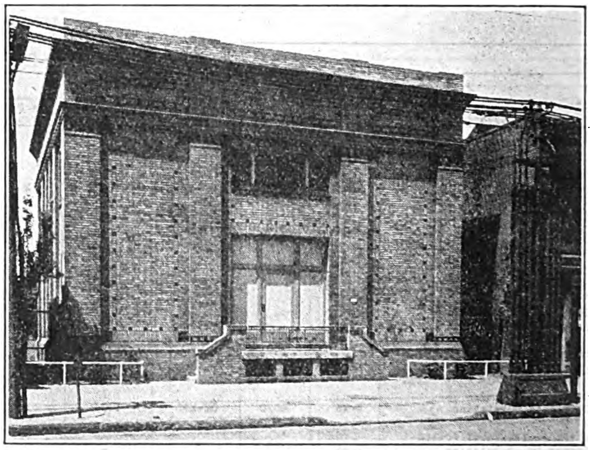

FIG. 79—EXTERIOR, STANDARD TWO-UNIT SUBSTATION, CLEVELAND RAILWAY CO.

The total load of the individual stations in d-c. amperes is indicated in the dispatcher's desk by use of a remote metering system.

5. Utilization of the One Size Rotary Converter

It is interesting to note that all machines on the system, both those in manual and automatic operation, are of one design, type and capacity, namely 1500-kw., 60-cycle.

6. Location of Current Limiting Resistance

Current-limiting resistances for both converter cir-

cuits and bus ties are located on the roof of the substation building, protected from the elements by steel cabs. In this position there results maximum natural ventilation and reduced size of building interior.

Referring to the accompanying illustrations of equipment, Fig. 80 is a general view of the main floor. In the background is a steel cabinet containing the rotary converter low-voltaged starting switches. To the right of the steel cabinet is the substation supervisory control cabinet. Pneumatic contactors for shunting converter resistance are shown under the left-hand corner of the balcony. Fig. 81 is an illustration of the d-c. positive feeder, pneumatically operated contactors (one-half of the equipment shown). The equipment in the lower left-hand corner is the negative drainage panel for the drainage of subterranean structures.

Commonwealth Edison Company, Chicago, Ill.—West Lawn Substation

This is an automatically operated mercury-vapor rectifier substation and furnishes 600-volt direct-current energy for traction load. It receives 12,000-volt, 3-phase, 60-cycle energy from the generating station through the underground cable system over two 500,000 c.m. 3-conductor cables. This substation together with another remote-controlled substation form a loop which is fed from the nearest attended substation.

The switching of the 12,000-volt feeders is controlled from the nearest attended substation by means of a telephone relay system which gives indication of the operation of the switches and which operates alarm signals when abnormal operation occurs. The 12,000-volt bus structure is of concrete construction, group-phase type, with one bus installed at this time and space for one future bus in the present building.

The rectifier unit has a capacity of 300 kw. at 600 volts with an overload rating of 150 per cent load for 2 hr. and 200 per cent load for one minute. The unit, which was made by the American Brown-Boveri Electric Corporation, consists of a 4410-kv-a. transformer, the rectifier bowl, an absorption reactance coil, vacuum pumps, ignition and excitation equipment.

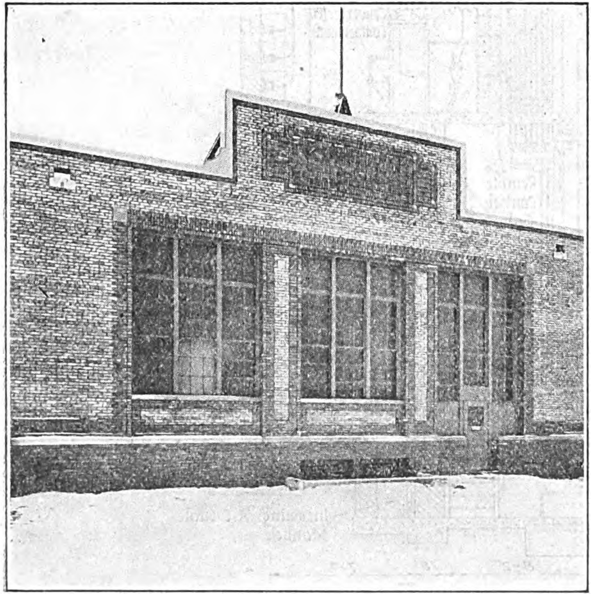

FIG. 84—EXTERIOR, WEST LAWN SUBSTATION.

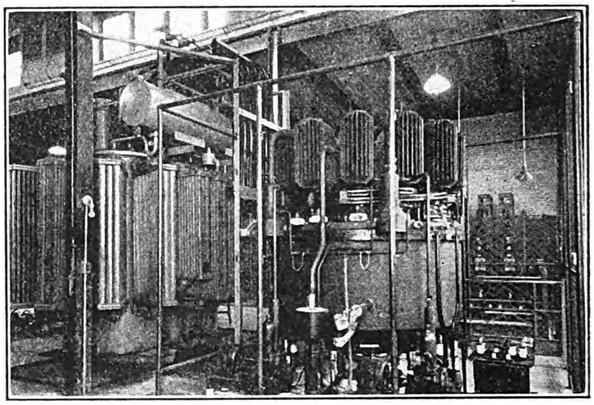

FIG. 85—MERCURY ARC RECTIFIER, WEST LAWN SUBSTATION.

The transformer is oil insulated, self-cooled, indoor type, with cooling radiators and conservator tank. It is 3-phase with the primary winding star connected and having five full taps connected to an internal tap changer, which cannot be operated under load. The secondary winding is double 6-phase fork-connected, giving a pressure of 540 volts which is applied to the rectifier anodes.

The rectifier bowl has twelve water-cooled anodes, two excitation anodes and an ignition anode. It is water-cooled, using city water for this purpose. Ignition and excitation is accomplished by single-phase a-c. low-voltage current applied through a small insulating transformer which also serves to insulate the a-c. feed for the mercury-vapor pumps. The excitation current is dissipated in the form of rectified current through a small external resistance. The excitation system is virtually a small single-phase rectifier within the main unit.

The absorption reactance coil is connected in the

neutral leads of the transformer secondary windings, which also is the 600-volt negative return, and serves to control the voltage regulation of the outfit as well as to dampen the undulations in the rectified voltage.

The rectifier has two complete vacuum pump sets, each consisting of an oil immersed rotary pump, which remove the major portion of air gases from the rectifier, and a mercury-vapor pump which serves to remove the remaining gases.

The control switchboard consists of three panels on which are mounted the necessary control and protective relays. The rectifier is normally started and stopped by means of a time clock which sets in motion the various relays used for this control. By opening certain switches the control can be changed over to hand operation. The rectifier is protected from a-c. and d-c. overload, short circuit, reverse current, overheating, low vacuum, loss of water and continuous overload which is under the definite time overload settings of the relays.

FIG. 88—Plan, West Lawn Substation.

Since this substation feeds directly to the customer, metering is required. This is accomplished by three single-phase a-c. watt-hr. meters connected in the primary side of the main transformer and by two Thompson d-c. watt-hr. meters connected between the main 600-volt bus and the 600-volt feeder bus, to which the customer's feeders are connected.

The feeder equipment consists of General Electric Type MC-2 4000-ampere, automatic reclosing air circuit breakers. They open on overload and reclose only when the load current is reduced to a predetermined value. There is no limit to the number of reclosings.

Special Features

Vacuum control is independent of the operation of the unit. By means of an electric hot wire vacuum gage and vacuum control relay, the mercury and rotary vacuum pump are started and stopped dependent on the condition of the vacuum.

The amount of water flowing through the rectifier bowl is controlled by means of a sylphon temperature relay placed in the water discharge system. This relay controls a valve in the cold water line to the rectifier.

The city cooling water is filtered with a gravel filter to eliminate fine silt which, when present, is deposited on the bottom of the rectifier bowl. An auxiliary water pump is installed to compensate for loss of pressure through the filter. It is automatically controlled by means of a pressure regulator.

The basement portion of the substation is heated by a hot water system and an automatic gas-fired water heater regulated to maintain a temperature of approximately 40 deg. fahr.

A 20-pen Bristol operation recorder is used to record starting and stopping of rectifiers, opening and closing of a-c. and d-c. circuit breakers and all feeder circuit breakers.

An annunciator is connected to give a visible signal when excess temperature or low vacuum occurs in the rectifier bowl and when the substation is locked out.

FIG. 89—Section, West Lawn Substation.

The Denver Tramway Corporation, Denver, Colo.—Colfax Substation

This substation is one of the eleven operated by the Denver Tramway Corp. for street car service. Since this substation is the most modern of the system, the data in this report will apply only to it.

Old Equipment

The equipment in this substation has previously consisted of three 300-kw., Westinghouse rotary converters with three single-phase air blast Westinghouse transformers. The station was operated manually, taking power from the 3-phase, 13,200-volt, 25-cycle, a-c. transmission line and converting it to 600-volt d-c. power for railway service. The switchboard consisted of Westinghouse a-c. and d-c. machine panels and nine feeder panels for 600-volt d-c. railway service.

Recently this substation has been completely rearranged and new equipment added. The three 300-kw. rotary converters with their three single-phase transformers and a-c. and d-c. machine panels have been rearranged as to location in the station. All the old d-c. 600-volt feeders have been removed, and this old equipment is now used only as standby equipment.

New Automatic Equipment

New equipment consisting of a 1000-kw., General Electric rotary converter with a 1050-kv-a. self (oil) cooled General Electric transformer and a complete General Electric switchboard consisting of starting and running panel, d-c. machine panels and four d-c., 600-volt feeder panels for full automatic control of the station, have been installed. In addition to the automatic control feature of the station, supervisory control equipment for control of this station from the Platte Street generating station was incorporated into the design. This supervisory control equipment is of the audible selector type.

A-C. Feeder System

The various substations of the system are on a 3-phase, 25-cycle, 13,200-volt a-c. ring circuit running from the Platte Street generating station. This circuit, under normal operating conditions, is sectionalized at Colfax substation, the circuit thus being divided into a north and a south circuit. Under the old conditions of manually operating the station, this sectionalizing of the circuit was done by means of Maxwell switches mounted outside of the station. This substation normally takes power from the south circuit, but in case of line failure power can be obtained from the north circuit by means of manually sectionalizing the high tension line. Thus by installing automatic control equipment in Colfax substation it was necessary to have some means of sectionalizing the high tension ring circuit by means of remote control. For this reason supervisory control equipment was installed in the station so that the dispatcher at Platte Street generating station can control the sectionalizing of the high tension ring circuit as well as control the station equipment. Included in the new station equipment are two motor-operated oil circuit breakers which are used to sectionalize the high tension circuit. The motors are operated by a storage battery installed in the station. The operation of these oil circuit breakers is controlled from the dispatcher's station of the Platte Street generating station.

Supervisory Control

The Audible Selector Supervisory System has been designed to operate over the two telephone wires now installed between Colfax substation and the dispatcher's station at the Platte Street generating station. The dispatcher at the generating station can perform the following operations at the substation:

1. Open and close two non-automatic oil circuit breakers.
*2. Start and stop the rotary converter.
*3. Close to automatic or trip and hold out the four d-c. 600-volt feeders.
*4. Trip one manually operated oil circuit breaker.

The following indications will be made at the dispatcher's station by means of a high frequency howler:

1. Open and closed position of the two oil circuit breakers used to sectionalize the high tension ring circuit.
2. Running and stopped position of the rotary converter indicated by the closing or opening of the d-c. line contactor.
3. Open and closed position of the four d-c. feeders.
4. Open and closed position of the manually operated oil circuit breaker.

Automatic Control of the 1000-Kw. Rotary Conveyor and D-C. Feeders

The automatic switching equipment functions as follows:

When the indication is given by the supervisory control equipment and on load demand, the rotary converter is connected to partial voltage taps on the power transformer. When synchronous speed is reached, the field is separately excited for a short time to insure correct polarity and is later made self excited. The transfer is then made from the partial to the full voltage taps of the transformer, the brushes are lowered on the commutator and the machine is connected to the d-c. bus through the load limiting resistors if the polarity is correct. These resistors are then successively shunted and the machine takes load.

The rotary converter is shut down within a definite time after the load on it has been reduced below 5 per cent (adjustable from 5 to 20 per cent) of machine rating, and the bus voltage is normal, or by the supervisory control equipment.

---

*These operations have been discontinued as there is danger of the station being shut down unnecessarily due to the dispatcher being unaccustomed to the operation of the supervisory system.

The machine load limiting equipment is included to:

1. Limit the amount of overload and prevent it being carried continuously.
2. Allow the shifting of a portion of the load to other stations feeding into the same network.
3. Prevent the machine from being connected directly to a heavy load in such a way as would cause a disturbance to the system.
4. Shut down the machine when the load limiting resistors tend to overheat and allowing restart only when the resistors have cooled.

The automatic equipment provides protection against:

1. Starting with
- (a) Low a-c. line voltage.
- (b) Single-phase or reverse-phase rotation of a-c. supply.
- (c) D-c. brushes not raised from the commutator.

2. Operating with
- (a) Low a-c. voltage.
- (b) D-c. reverse current or d-c. underloads.
- (c) Overheated rotary converter windings.
- (d) Single or badly unbalanced phases.
- (e) Overheated load limiting resistors.

NOTE: The converter may restart or be reconnected to the d-c. bus when the proper conditions have been re-established.

3. Operating when
- (a) Starting sequence is incomplete.
- (b) A-c. short circuit occurs.
- (c) Rotary converter field fails.
- (d) Rotary converter overspeeds.
- (e) Rotary converter flashes to ground.
- (f) Bearings overheat.

NOTE: Under any one of the above conditions, the equipment will shut down and lock out the station. Manual attention will be required before the converter can be restarted.

The d-c. reclosing feeder equipment with MC-2 Breaker will:

1. Trip at a predetermined current setting in case of a gradual steady increase in load.
2. Reclose on stub or multiple feed from either side.
3. Reclose the feeder within a minimum definite time after the feeder has been disconnected, provided the load is not excessive.

Station Ventilation

Since this substation runs fully automatic, ventilation becomes an important factor. The air is taken from outside the building and brought into the station through an air tunnel terminating at both ends of the converter. The fan action of the revolving armature tends to draw in the air and cause it to flow into the machine parallel to the shaft. Installed on the roof of the station over the rotary converter is a 60-in. Aeolus natural draft ventilator. The combined action of the revolving machine armature and the suction of the roof ventilator ventilates the station very satisfactorily.

The ventilator is so situated on the roof that no station apparatus is directly under the ventilator opening. Thus if any snow is driven in the ventilator, the condensate thus caused cannot drip on any piece of equipment and cause damage. The ventilator is equipped with a damper operated from the floor, and in the air tunnel another damper is installed. By manipulation of these dampers the ventilation of the station can be regulated.

The Detroit Edison Co., Detroit, Mich.—Roseville Substation

This substation supplies both a-c. distribution to the village of Roseville, and railway power. Data included in these notes apply to the d-c. part of the station only. The automatic rotary converter in this station is one of several located at various points along the route of the Port Huron Division of the Detroit United Railway. These are all identical as regards control and operation. The rotary converter with control was furnished complete by the Westinghouse Electric & Manufacturing Co. and is their standard type of automatically controlled machine.

This substation has no fire protection, except that furnished by fireproof construction and by Pyrene fire extinguishers placed in accessible positions. The entire substation, a-c. and d-c., is designed for operation without attendance, as it is looked after by an operator who is also in charge of several other automatic substations.

Duquesne Light Co., Pittsburgh, Pa.—Maple Substation

This substation consists primarily of two 1000-kw. rotary converters with the necessary switching equipment to furnish service to the Pittsburgh Railways Co.

The energy is received at 22,000 volts over two lines. A feature of the station is that no 22,000-volt oil circuit breakers are used.

The transmission line is sectionalized by means of air break switches, and the rotary converter transformers are connected to these lines by means of air break switches. Automatic switching, in case of rotary converter trouble, is accomplished by oil circuit breakers between the transformers and the rotary converter. The connections are so arranged that the air break switch controlling the transformer will open a predetermined time after the rotary converter is shut down, thus de-energizing the transformer.

The substation is entirely automatic, and uses a battery for the source of control. Indication is provided in the system operator's office to show that the substation is functioning properly.

Special attention has been paid to ventilation and to the reduction of objectionable noise. The intake air is drawn into ducts under the floor from the top of the building through ducts extending up the building wall. The air is drawn into the rotary converter through a grating in the floor at each end of the machine outside of the pedestal. A portion of the air is discharged from the rotary converter through a duct underneath the floor connecting to a duct up the building wall. The remaining portion is discharged into the room and is drawn from the building through a roof ventilator.

The interior walls of the building are of tile. The use of this tile and the method of ventilation have resulted in the elimination of objectionable noise in the vicinity. The ventilation has also been very effective.

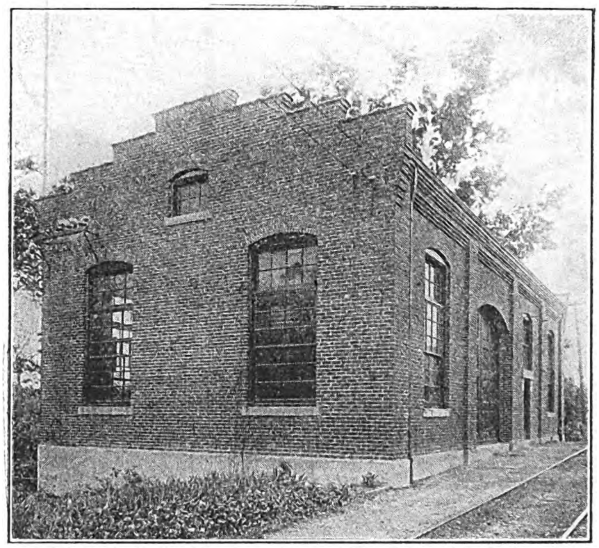

FIG. 107—EXTERIOR, BLUE AVE. SUBSTATION.

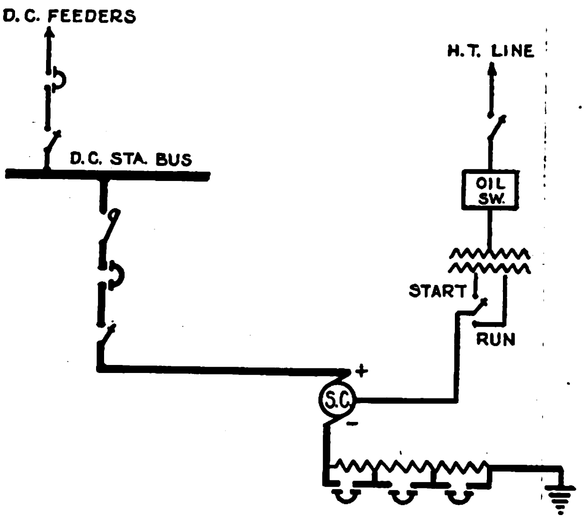

FIG. 109—SINGLE LINE DIAGRAM, BLUE AVE. SUBSTATION.

Kansas City Public Service Company, Kansas City, Mo.—Blue Avenue Substation

Besides operating street cars in Kansas City, the Kansas City Public Service Company also furnishes transportation to several small outlying towns. One such suburban electric line is double-tracked to Independence, Mo., which is located to the east, a distance of 10 miles. D-c. power for operation is furnished at a potential of 600 volts through Blue Avenue substation, which is located three miles from the end of the line. This substation is reinforced by substations in Kansas City and a 500-kw. machine at the west end of the line. This machine, however, runs only 4 hr. per day. Blue Avenue Substation is located near the center of its load.

The substation building is of typical design, being of brick masonry. It has a two-machine capacity and room for housing all of the auxiliary apparatus. In 1908 a manually operated General Electric 1000-kw. rotary converter was installed, and in 1920 this was made automatic, using all General Electric equipment. To date the substation capacity has been found large enough to meet all of the energy demands, and consequently only one machine has been installed.

Power is sent from Kansas City to this substation over an aerial line at 6600 volts, 25 cycles. At the northeast corner of the substation, where the lines enter, are the lightning arresters, the oil switch, power transformers and the operating transformer. The power leads then run to the rotary converter through the controller. From the direct current side of the rotary converter the positive leads run directly to the switchboard, where metering and switching equipment are located. Here distribution is made to the load over five feeders. To the right of the d-c. switchboard is the panel on which are mounted the operating relays and contactors. Current returns to the substation through the rails and parallel copper cable. At the substation a tap from the rails leads directly to the load-limiting resistors located in the center of the room. These are used to prevent a thermal overload on the machine.

The machine automatically comes on the line when the trolley voltage falls below 375 for 5 sec., and shuts down when the current reaches a minimum of 300 amperes for 7 min. It operates approximately 21 hr. a day and has an average load factor of 43 per cent.

FIG. 111—Section, Blue Ave. Substation.

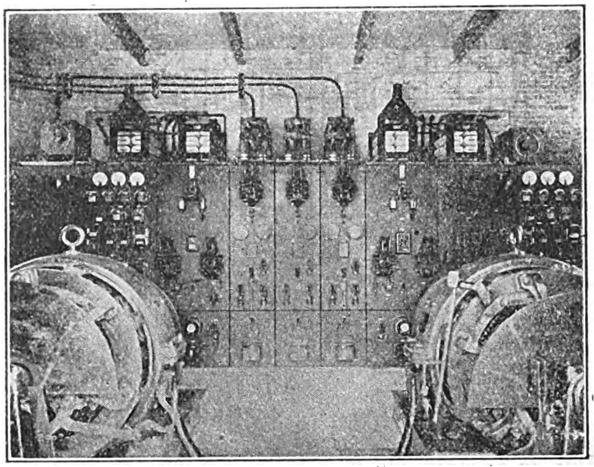

FIG. 113—Synchronous Converters and Switchboard—St. Martins Substation.

The Milwaukee Electric Railway & Light Co., Milwaukee, Wis.—St. Martins Substation

This substation contains two 500-kw., 600-volt, d-c. rotary converters with full automatic operation and three automatic reclosing 600-volt feeders with short-circuit detector type equipment. It is located on one of the interurban railway lines at a point where the line divides into two branches, and consequently feeds the trolley in three different directions. This substation is similar to four other substations on this line which have, however, only one 500-kw. machine each.

The transformers are connected to the 26,400-volt, 60-cycle bus through disconnecting type fuses, and the transformers are normally alive at all times.

One of the features of this substation is its ventilating scheme. Air is brought into the station by means of underground ducts through gratings at each end of the rotary shaft. Hot air is taken out through ventilators in the roof.

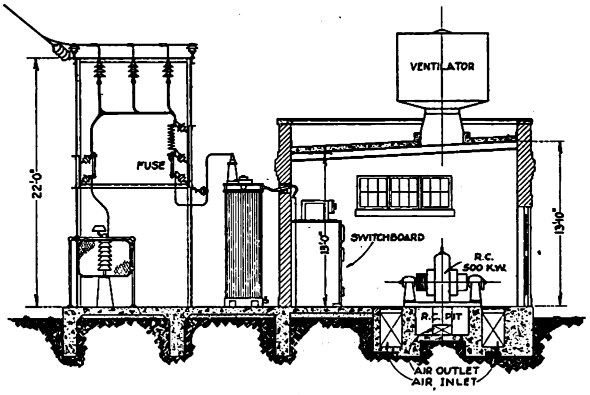

FIG. 116—SECTION, ST. MARTINS SUBSTATION.

Public Service Electric & Gas Co., Newark, N. J.—Miller St. Substation

This is an automatic substation supplying railway, lighting and power loads. Because of its location in a residential district of Newark, special provisions for ventilation and the elimination of noise were necessary.

Major equipment installed in this substation consists of the following:

Four 4000-kv-a., 3-phase transformers arranged as two 8000-kv-a. banks 26,400-13,200/4150Y.
Two 1500-kw. railway motor-generator sets, each consisting of a 4150-volt synchronous motor and a 600-volt compound-wound generator.
Five 13,200-volt incoming feeders.
Ten 4150-volt, 3-phase, 4-wire power and lighting feeders, equipped for automatic reclosing.
Nine 600-volt railway feeders, equipped with automatic high-speed circuit breakers.

The two transformer banks are controlled by automatic switching equipment through a multiple-pole, double-throw switch. By this switch either bank may be made to lead and the other to trail. The trailing bank is cut into service when the load on the leading bank exceeds its rating; with both banks in service the trailing bank is disconnected when the total load is 90 per cent of the capacity of the leading bank.

Automatic protection for the transformers is provided for the following conditions:

Overload.
Grounded or short-circuited windings.
Overheated windings.
Failure of leading bank.
Throwing of changeover switch.

By means of the automatic control equipment for the motor-generator sets, either set may be made to lead or trail. The leading set starts on low bus voltage, and at 150 per cent normal load on this unit the trailing set is started by a contact-making ammeter.

In the event of overload on either set, the series field of the overloaded generator is open-circuited and a load-limiting resistor is connected in the line. The two load-limiting resistors are provided with a thermostat which disconnects the unit when the resistor is overheated. Other protection for the sets includes the following:

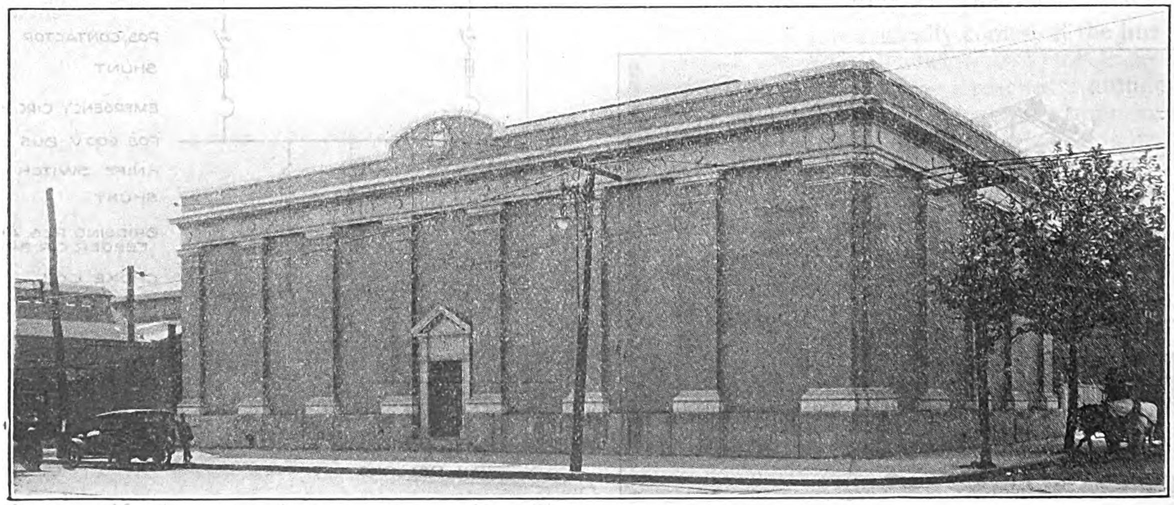

FIG. 117—EXTERIOR, MILLER ST. SUBSTATION.

Grounded generator armature.
Reverse power.
Incorrect generator polarity.
Generator field failure.
Grounded or short-circuited motor windings.
Motor field failure.
Single-phase starting.
Overheated motor windings.
Low a-c. voltage.
Overspeed.
Incomplete starting.
Overheated bearings.

The incoming feeders are provided with reverse power relays. The automatic reclosing equipment for the 4150-volt feeders provides for three reclosures at increasing time intervals and lock-out until reset by hand. The high-speed breakers on railway feeders, when tripped under short circuit, reclose when the feeder is cleared. A thermal relay is also provided which trips the high-speed breaker on sustained overload less than the breaker setting, and which recloses the breaker when the feeder has cooled sufficiently.

FIG. 121—SECTION, MILLER ST. SUBSTATION.

Public Service Company of Northern Illinois, Chicago, Ill.—Glen Ellyn Substation

This substation, located at Glen Ellyn, Ill., was placed in service on April 20, 1927, and is one of nine new 60-cycle rotary substations serving the Chicago, Aurora & Elgin Railroad.

The substation structure was arranged, from an architectural standpoint, to fit into the surrounding community and to be attractive to the patrons of the railroad. The building is located in the eastern section of Glen Ellyn and contains one automatic 1500-kw. rotary converter and four feeders to the railroad's third rail.

This substation is unattended and is controlled by a selector supervisory system from the system operator's office at Wheaton, Ill., approximately three miles distant. This supervisory system is capable of starting and stopping the rotary converter, in addition to opening and closing the high-speed breakers on the feeders serving the railroad. When the system operator turns the key for starting the rotary converter under the supervisory system, the rotary converter will start only when the load requirements reach the point when the master switch operates and the sequence of starting follows until the rotary converter is put on the line.

The machine is protected by under-voltage relays on the 33,000-volt side and will trip out due to overheated bearings, overheated load-limiting resistors, reverse power, flash-over or grounded winding and extreme d-c. overload after the load-limiting resistors have cut in but failed to handle the excess load.

All the equipment in this substation is inspected once a day by the operating department and, should any unusual trouble develop, an emergency repairman is immediately sent to the substation to inspect the difficulty and get the machine back on the line as soon as possible.

In order to safeguard the surrounding neighborhood from the characteristic noise of a 60-cycle rotary converter, all the metal doors are lined with a hair and asbestos felt (which is not fire sustaining) and is in turn covered with a fireproofed burlap to afford a mechanical protection to the hair felt. This method of padding the sound-distributing sections of the building has proved to be very satisfactory. The excess heat is discharged through a tower in the roof by means of two exhaust fans, which are operated in multiple when the rotary converter is running, either one of which is capable of being run alone in case of difficulty on the other.

NON-AUTOMATIC RAILWAY SUBSTATIONS

Commonwealth Edison Company, Chicago, Ill.—Laflin Street Substation

This is a 1500-kw., mercury-vapor rectifier substation and furnishes 1500-volts d-c. energy for railway load. It receives 12,000-volt, 60-cycle, 3-phase energy from the generating stations through the company's underground cable system. Due to the use of 500,000 circular mil three conductor cables on the 12,000-volt system, this small load is carried on two loop lines, one of them being a reserve supply. This substation also furnished 4000-volt a-c. distribution to the same customer for light and power use in and around their structures.

The 12,000-volt bus structure consists of four safety inclosed switchboards with removable truck-type panels. These are used for two lines, one rectifier, and one light and power transformer bank.

The rectifier consists of one 1575-kv-a. transformer, two anode reactors, two 750-kw. mercury-arc rectifier tanks, two vacuum pumps, one 3-unit, arc-striking motor-generator set, one positive and one negative high-speed breaker and necessary protective equipment. The negative side, which is the neutral of the transformers, also has one interphase transformer and a negative reactor. The main transformer has full capacity primary taps, and load can be varied with tap switch, but not while under load.

The switchboard consists of control panels for 12,000-volt oil circuit breakers, rectifier, two 1500-volt feeder panels, and necessary panels for the 4000-volt a-c. distribution. The 1500-volt panels are safety-inclosed switchboards with removable truck-type panels, and the type of construction is similar to the 12,000-volt panels.

Special Features

The customer's energy is billed from a watt-hr. meter, shunt type. The shunt is located in the negative lead of the rectifier, and the instrument is located in the basement away from d-c. fields.

The d-c. pressure being 1500 volts makes it objectionable for use on pressure coils on d-c. instruments. Standard 110-volt instruments are used, and the 110-volt service is obtained by using the 110-volt drop on the negative end of a 67,000-ohm resistance. A separate resistance is used for each pressure coil.

An annunciator system is employed which uses standard telephone switchboard parts, and indicates with a light when attention is required. An audible alarm is also used with this device.

The feeder breakers are non-reclosing, but their setting is higher than the machine negative breakers. A short circuit on a feeder opens the negative machine breaker, which shunts a load-limiting resistance. Should the fault be cleared, the relay arrangement recloses this negative breaker automatically. Should the fault persist, the negative will remain open, and the positive breaker will open also. When more capacity is added to this substation, the short circuits on feeders will normally open the feeder breaker only.

Equipment is permanently installed to bake-out rectifier anodes, and ammeters are installed in the negative lead of each tank to indicate whether both tanks are working.

FIG. 132—SECTION, LAFLIN ST. SUBSTATION.

Dallas Power & Light Company, Dallas, Texas—Typical Substations

The d-c. substations are constructed as part of the a-c. substations, and the direct current is used to serve only the city's street railway system. Thus the same building houses both a-c. and d-c. equipment, and the same high tension buses serve the transformers for a-c. service and the conversion equipment for d-c. service.

Alternating current is delivered through 13,000-volt transmission lines to the substation 13,000-volt buses, to which are connected motor-generator sets. Each set consists of a 13,200-volt, 3-phase, synchronous motor directly connected to a 600-volt, compound-wound d-c. generator, with a continuous output rating of 1000 kw. There are three such sets to a substation, feeding a common d-c. railway bus, from which the necessary number of railway feeders are taken.

Starting of the synchronous motor is accomplished, in the majority of installations, through a starting compensator which provides approximately 60 per cent of full voltage for this purpose. However, the more recently installed sets are constructed for full voltage starting. These are connected directly across the 13,000-volt buses for starting. On full voltage starting they come up to synchronous speed in an average time of 4.5 sec., and require a starting current of approximately five times full load running current. At starting, the average maximum drop in voltage on the 13,000-volt bus at the generating station is 3 per cent.

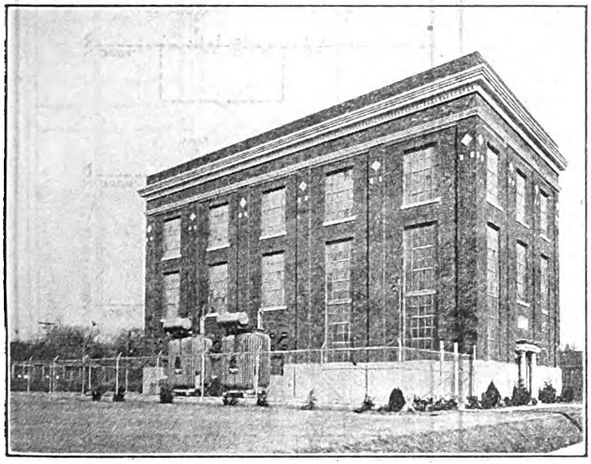

FIG. 133—EXTERIOR, SOUTH DALLAS SUBSTATION, DALLAS POWER & LIGHT CO.

Installations which utilize a starting compensator are provided with necessary relays which prevent the operator leaving the motor running on the starting tap longer than a predetermined interval, as at the expiration of this starting interval the motor is automatically disconnected from the a-c. buses. Such installations also have the starting, magnetizing and running oil circuit breakers so interlocked that it is impossible to have a starting and running breaker closed at the same time.

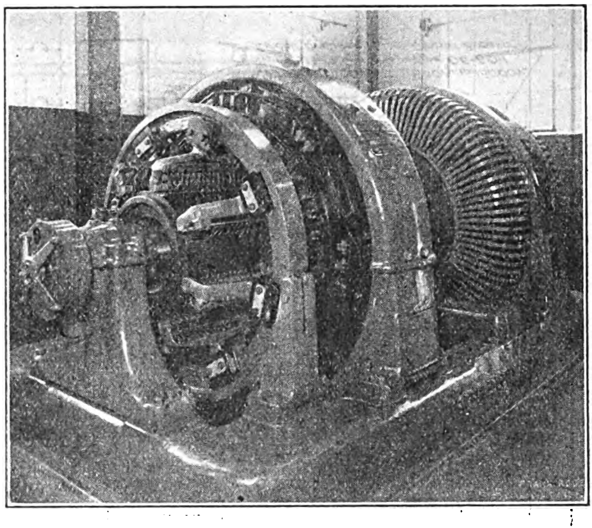

FIG. 134—1000-KW. MOTOR-GENERATOR SET, DALLAS POWER & LIGHT CO.

All sets are equipped with Type CO induction relays on the motor side; and on the generator side the air carbon circuit breaker has overload and undervoltage trip coils.

FIG. 138—SECTION, SOUTH DALLAS SUBSTATION, DALLAS POWER & LIGHT CO.

The Delaware County Electric Company, Philadelphia, Pa.—Crosby Substation

This substation of the Delaware County Electric Company, a subsidiary of the Philadelphia Electric Company, is located in the city of Chester, about 14 miles southwest of Philadelphia.

This substation is a combined a-c. distribution and railway substation. As will be noted from the accompanying single-line diagram, the 13,200-volt buses and feeders are common to both classes of service. While most of the distribution load is at 2400 volts, there is also some at 13,200 volts. The railway load, at 600 volts, is delivered to two street railway companies operating in the vicinity.

The substation is not now fully developed. Three of four ultimate rotary converters and two of four ultimate distribution transformers, together with three incoming and one outgoing 13,200-volt lines, are installed at the present time. In order to reduce short circuit duty, each 13,200-volt bus, ultimately, will be operated with bus sectionalizing switch open, giving four separate bus sections. Each section will then supply a portion of the railway and a-c. distribution loads.

Relay protection is provided as follows:

Incoming 13,200-volt lines—Reverse power relays.
Rotary converters:
  A-c. side—Overload relays (connected on 13,200-volt side of converter transformers).
  D-c. side—Overload, reverse current, and low-voltage trip.
D-c. feeders—Overload trip.

The electric sign on the top of the station (shown in the accompanying exterior view) faces a railroad carrying heavy passenger traffic. This sign was erected and is maintained by the Delaware County Electric Company as a part in the development of its public relations policies.

FIG. 145—Section, Crosby Substation.

New Orleans Public Service, Inc., New Orleans, La.—Polymnia Substation

This substation, located in a semi-commercial district, has its main bus operating at 13,200 volts. Power from the main generating station is brought into the bus through three underground feeders, and from this bus two outgoing feeders tie it to the other substations.

Two 6-phase rotary converters, supplied from the 13,200-volt bus through transformers, furnish power to the 600-volt d-c. railway system through ten railway feeders.

Power is supplied from the 13,200-volt bus through one bank of transformers to nineteen mercury-arc rectifier circuits for street lighting.

There is also a 4000-volt bus in this substation connected through two 3000-kv-a. transformer banks to the 13,200-volt bus. From the 4000-volt bus are five outgoing feeders for local distribution and two Whiteway circuits for street lighting. All feeders from the substation are brought out underground.

FIG. 151—SECTIONS, POLYMNIA SUBSTATION.

Utica Gas and Electric Co., Utica, N. Y.—Whitesboro and New Hartford Substations

These substations are located approximately four miles from the center of the city of Utica and are combination railway and distribution substations.

Whitesboro substation is supplied by two 44,000-volt circuits from Washington Street station, and in general consists of a distribution transformer bank, two distribution circuits with necessary switching equipment, including induction regulators, and two 500-kw., General Electric synchronous converters. The New Hartford substation is very similar to the Whitesboro substation, except that there is only one commercial circuit and the railway equipment is of Westinghouse manufacture. This substation is also supplied by a 44,000-volt feeder from Washington Street substation.

Relay protection is provided as follows: The machines are protected against flashover with flashover and overload relays. The current transformers for the overload protection are located in the low-voltage leads, and both the flashover and overload relays trip the high tension breaker. This breaker has an auxiliary contact which, when the breaker opens, opens the d-c. machine breaker. The machines are protected against low voltage by low-voltage relays connected in the low-voltage leads of the a-c. supply. These relays trip the high tension breaker, which in turn, as previously explained, opens the d-c. breaker. Other protection consists of the usual reverse current on the d-c. side, d-c. overload and overspeed protection.

Because of the similarity of these substations, drawings and photographs of Whitesboro substation only are reproduced in this report.

UNIFORM RECORDS OF ELECTRICAL OPERATION OF POWER SYSTEMS

This report describes typical forms for recording, analyzing and summarizing, on a uniform basis, the electrical operation of power systems under abnormal conditions.

Purpose

Records of interruptions, equipment troubles, operating mistakes, relay performance, etc., have progressed to the point where the practice of several companies may be correlated and set down for the information and suggested guidance of the industry. This correlation is a stage between description and standardization. There is now sufficient uniformity of definition, method and uses as to permit coordination without attempting a standardization that might, at this time, be restrictive of progress as well as limited in acceptance.

Scope

The effects of abnormal conditions are measurable in damage to property, injury to persons and interruptions to service—all of vital interest to the management.

The histories of abnormal conditions are essential in determining how these undesirable effects may be minimized or prevented when the conditions recur.

General information relative to abnormal conditions which occurred without causing any trouble is necessary in determining percentage of successful operation.

Detailed information relative to abnormal conditions which resulted in damage, injury or interruption is essential.

The scope of the abnormal operation report is the extent of the system and its performance during fault conditions. The report is not limited to relays and their accessories. It does not assume that the design of the system and the methods of operating it are above suspicion or beyond improvement, nor does it assume that incorrect operations always result from deficiencies in relays and their accessories, or from any inadequacy in the present state of the art of protection. Neither does it assume that system design and operation should always be such as to give the best protection. The cost of an interruption may be less than the cost of preventing it. This is seldom the case, however, and where the limitations and possibilities of relay protection are known and considered in system planning and in system operating, it is possible (as far as protection is concerned) to generate power economically, to provide good voltage regulation, to minimize equipment damage and to give adequate service, all without excessive investment or abnormal operating costs.

Basic Factors

Many abnormal conditions never reach the stage of "cases of trouble," and many "cases of trouble" never injure plant, personnel or service, because good management or good fortune intervenes. It would, therefore, be desirable to develop an efficiency factor—a ratio between the uncontrollable opportunities for trouble and the resulting effects. But in general many causes of abnormal conditions, such as storms, are measurable only by their effects on the power system. It is all the more important, therefore, to measure these effects quantitatively, since, if trouble cannot be measured as an instantaneous ratio, it must be accumulated for a period and compared with itself over other time intervals, or with the accumulated total on other systems for a common interval.

Of the three effects of abnormal operating conditions, only "interruptions to customers" has lacked an agreed quantitative basis. Damage to property has always been measurable in dollars and cents. Injuries to persons have been measurable for some time, using methods developed by the Accident Prevention Committee.

There has also been lacking a common basis for classifying the accuracy of functioning of the various elements that make up system performance.

This report, therefore, will deal primarily with records of the accuracy of system performance under abnormal conditions, including records of interruption to customers.

It is intended that those adopting these records may take such liberties with them as are necessary to fit their respective organizations, but that the essential results will be kept on a uniform basis.

Fundamental Features

The basic features of these records are as follows:

1. A complete periodic report on the accuracy or legitimacy of performance of the system under abnormal electrical conditions is provided for the department heads responsible for system planning, system operation, electrical design, relaying, load dispatching, maintenance, construction, public relations, commercial activities, etc.
2. Correct performances are summarized. Incorrect performances are tabulated individually, with adequate sub-classifications, accompanied by an analysis of cause, responsibility, effect and remedy.
3. The definition of "correct" performance is based upon an economic balance between the various factors in design and operation. "To perform correctly, the system, including equipment, personnel and routine, must clear up an abnormal condition with less damage and interruption than any other economically justifiable system."

Publication No. 289-52, Serial Report, Electrical Apparatus Committee.

4. A classification of incorrect system performance has been developed that distinguishes between man failure and equipment failure, between errors within and without the relay department, between individual defects and group defects of equipment, and between poor planning, designing, construction, operation and maintenance.
5. A running record of incorrect relay operations is available by location, enabling the relay engineer to study the effects of changes in protection.
6. There is included a periodic report on interruptions to customers which is sufficiently quantitative to be comparative from time to time as well as between companies.
7. Results may be classified by station, customer, voltage, circuit, cause, origin, time, etc.
8. A brief periodic summary may be prepared for executives.
9. A typical set of coordinated daily operating records is shown herewith for the purpose of illustrating the economy in clerical work which may be accomplished by coordinating all operating records at their sources.
10. Tentative definitions relating to performance are included in this report, pending completion by the A. I. E. E. and N. E. L. A. of standard nomenclature.

Typical Records

To illustrate the essential features of a uniform report on "System Performance Under Fault Conditions," typical records from one company are presented. The forms represent the latest practice of this company, including all revisions made from time to time to coordinate its records with those of other companies.

The report is called the "Monthly Trouble Report" by some companies. The actual name is immaterial. Other names are suggested below:

"Disturbance Report"
"System Operation Report"
"Relay Operation Report"
"Protection Report"
"Interruption Report"
"Service Report"

The first page of the "Monthly Trouble Report" is a summary. The system performance is measured by three factors: cases of trouble, relay operations and interruptions. Some companies have been using only two of these three factors, and, as it has been impossible to come to an agreement on which two to use, if only two are selected, all have been included for use until further experience is available. Each has its advantages, and the inclusion of all three meets all objections, and represents the latest practice of the largest companies.

The third factor, interruptions, may be defined as to quantity, duration or extent, or preferably as to all of these. The loss of revenue load in kilowatt-hours (or kilowatt-minutes, for convenience) is a true measure of an interruption, detached from its individual peculiarities. Such a measure permits addition of interruptions, with each individual interruption affecting the total in proportion to its size. While the spoilage of goods in process, loss of time, etc., are more important to many industrial customers than the loss of revenue to the power company, such factors are best considered in connection with each individual interruption, as they are not susceptible of the quantitative measurement required in compiling periodic summaries.

"Kilowatt-minute" totals may be divided by the total system load in kilowatts to get "system minutes," or minutes of equivalent interruption to the entire system. The kilowatt load interrupted may be set up, on a demand, installed or consumption basis. The latter is preferable and is used in the forms herewith. The kilowatts used for each customer or substation interrupted is the yearly average kilowatts, which is obtained by dividing the yearly kilowatt-hour consumption of a given customer by 8760. In this method, the same kilowatt figure is used regardless of the time of day when the interruption occurs. This gives satisfactory results on the assumption that interruptions are independent of load, which is sufficiently accurate for localities where most interruptions are due to storms.

If sufficient data are available, the kilowatts may be tabulated for each customer and for each substation for each period of the day, requiring considerably more work in computing interruption records. Another method is to use the actual average kilowatts normally required by the customer at the time of the interruption, but this information is available only on systems with very complete graphic records on feeders, or with constant station attendance and complete indicating meter facilities, checked by the operator's and load dispatcher's knowledge of the customers' requirements.

The three factors outlined above, amount of trouble, amount of protective equipment operation, and amount of interruption to service, serve to throw light on system performance from slightly different angles.

While it would be desirable to follow the performance of the system through each case of trouble, this task is beyond the scope or ability of any one department. In the present state of the art of collecting and reporting operating statistics, about all that can be readily accomplished is to analyze trouble as to cause, interruptions as to cause and amount, and relaying as to cause, amount and accuracy. For some time the operation of protective equipment has been reported more completely than any other technical function. Furthermore, this function is a part of electrical operation, so that it is practicable for a report on electrical operation of the system under abnormal conditions to describe the operation of protective equipment more adequately than the performance of equipment under the jurisdiction of departments not responsible for electrical operation.

Recognizing the above limitations, the following specific definitions have been used in the preparation of the typical records herewith.

1. A case of trouble is legitimate if it originated outside of the system, that is, due to weather conditions, other companies, customers, public, etc. It is illegitimate if it originated within the company, that is, due to defective equipment, mistake by employee, or other inadequacy of routine or facilities. This definition contains the implicit assumption that the environment of the system is beyond control on any economically justifiable basis. In other words, a rough and ready criterion of economic justification is a matter of external or internal origin. Such usage may appear to be entirely empirical, but a study of actual system troubles on a large scale will show that this procedure is logical and adequate.
2. A relay operation is correct and legitimate if it assisted in isolating a maintained fault with less interruption and damage than any other economically justifiable installation. It is incorrect and illegitimate if it occurred unnecessarily or did not occur when necessary.
3. An interruption is legitimate if it originated outside of the system, that is, due to weather conditions, other companies, customers, public, etc. It is illegitimate if it originated within the company, that is, due to defective equipment, mistake by employee, or other inadequacy of routine or facilities. This definition contains the same assumption stated above. However, it is more quantitative, since, if the extent of the interruption is more than the economically justifiable minimum, the additional amount resulting from internal causes is charged up as illegitimate.

Some companies analyze electrical operation only as it concerns the high tension system, because it is difficult to get as complete information on distribution and utilization trouble as can be obtained on generation and transmission trouble. Accordingly, a space has been left in the heading of each report for indicating whether it refers to all divisions or merely to the transmission division of the company.

The summary is brief enough for transmittal to executives who desire a concise tabulation of results.

TABLE I

TROUBLE REPORT—ALL DIVISIONS

Summary

	Legitimate	Illegitimate	Per Cent Legitimate
Cases of trouble	72	44	62
Relay operations	181	11	94
System minutes	6	4	60

Following the summary in the Monthly Trouble Report are more or less detailed analyses of trouble, relaying and interruptions. These analyses are distributed to all department heads in the technical departments as well as to certain ones in the commercial departments.

There are many variables in connection with trouble, relaying and interruptions. Distributions by cause, damage, remedy, location, duration, date, time, justification, voltage, correctness, nature of trouble, type of equipment, class of service, etc., are all of interest and value. Cause is probably the most valuable classification and has been used in the typical forms herewith. The daily records are so arranged that it is practicable to go back at any time and make up special reports, using any of the above factors as a basis of classifications.

The practices of many power companies have been studied in arriving at the suggested classification for causes of trouble. The A. T. & T. Company schedule has also been consulted.

Every case of trouble is the result of a combination of conditions of the system and its environment. Three combinations are possible, viz:

1. Environment abnormal—system normal.
2. Environment normal—system abnormal.
3. Environment abnormal—system abnormal.

In Case 1 it is clear that the cause lies in the abnormality of the environment, and in Case 2 in that of the system. In these cases it is usually easy to decide the cause once the facts are known.

In Case 3 it is sometimes difficult to determine whether the abnormality of the environment or of the system is primarily responsible.

In some cases also several abnormalities may come into the picture, and the choice then is not always obvious. One rule is not to regard as abnormal any condition against which the system is normally protected, and to record as the cause or origin of the disturbance the *most* abnormal condition or occurrence observed. The decision as to which *is* the most abnormal must be a matter of judgment, and in doubtful cases it is natural to give the system the benefit of the doubt. Some companies provide space in their records for two

causes, a primary or originating cause usually arising out of the environment, and a secondary or contributing cause usually residing in the system or equipment. This scheme is of advantage in subsequent analysis and tabulation of disturbances. In some cases the abnormality of the environment may be the primary cause of the trouble, and the abnormality or inadequacy of the system the primary cause of the interruption.

In doubtful cases a predetermined schedule of preference as between various causes is most helpful, as will be noted from the definitions given later.

The Monthly Analysis of Relay Operation is set up in such a manner as to focus attention on the causes of incorrect operation. Correct operations are tabulated by circuits for reference in regard to breaker maintenance, etc. Incorrect operations are classified by causes, and are also described individually with regard to cause, responsibility, effect and remedy, including a history of the changes made to prevent a recurrence of the incorrect operation. Incorrect operations are a sufficiently small percentage of the total that they can be studied better if the correct operations are not included therewith.

The classification used for incorrect operation of relays or other protective equipment includes all causes which result in incorrect operation of protective equipment.

The first and third classes of incorrect protective equipment operation refer to the relay and its accessories, and the second and fourth classes refer to system planning and system operation. In the past, some companies have considered only the former. Other companies have considered the latter under the heading of "system operation" but independent of "relay operation." The fundamental objection to considering system planning and system operation separately from protective equipment is the now well recognized fact that protection is cheaply obtained if included originally, but in general is costly and incompletely adequate if added to existing major facilities and existing operating practices.

The Analysis of Interruptions is usually set up by stations or by high tension customers or by a combination of the two. The form herewith includes all

TABLE VI

TROUBLE REPORT—ALL DIVISIONS
January, 1929
ANALYSIS OF RELAY OPERATION
Details of Incorrect Operation

The six incorrect operations of the generator switch at McMinnville on Jan. 5 were due to this machine being overloaded in carrying the town of McMinnville while the 11 kv. Great Falls line was out. The load at McMinnville has been increasing to such an extent that it is very difficult to get selective action between the McMinnville generator and the Great Falls supply. Higher settings on the generator switch would reduce the protection to the generator which is non-attended. The problem is being studied further, and a complete revision of settings will be made on an experimental basis.

The incorrect operations on the 2300 volt side of No. 3 transformer and No. 4 transformer at Carter Street on Jan. 5 were due to a mistake by a relay man. When the switchboard was moved and the new 2300 volt bus installed, settings were revised and the relay man apparently got the settings for some of the circuits confused. The transformer switches had been set with the same time as the feeder switches.

The operation of the Maryville line during trouble on the Ocoee No. 2 110 kv. line at 10:33 a.m. on Jan. 5 was due to the trip circuits on the locking relays having been connected in parallel instead of series. Instructions on this point were clear, but were probably overlooked by the relay man in wiring the panel.

The incorrect operation of the Columbia line during trouble on the Southern Cities system on Jan. 5 was apparently due to an unbalance in the 110 kv. ground relay circuit during 44 kv. trouble. This has been eliminated by higher relay settings.

On Jan. 18 the 66 kv. ground relay at Athens operated on 22 kv. trouble, evidently due to unbalance. This has been eliminated by a higher relay setting. Apparently this trouble is a complication of variations in bushing current transformer ratio during single-phase and ground short circuits. This trouble was discovered several years ago and is corrected by raising relay settings whenever it recurs. In some cases this involves some sacrifice of the sensitivity of ground protection.

the high tension substations, whether supplying large customers or supplying distribution. Interconnections are also included.

On account of the fact that the entire load supplied to certain stations or customers may not be interrupted completely it is necessary, when using the kilowatt-minute method, to multiply the kilowatts interrupted by the duration of the interruption and divide the result by the total kilowatts of the station in order to get the number of minutes of interruption to the average customer from that station. This makes the use of kilowatt-minutes in the daily reports practically necessary. Typical daily reports will be described later.

In addition to the minutes of interruption to each station, the monthly analysis shows the number of times interrupted.

Clearances may be tabulated in the above manner, but the monthly report is usually concerned only with interruptions due to disturbances rather than by appointment.

There is very little difference in procedure among the various companies with regard to the authorship of the Monthly Trouble Report. It is made up by someone connected with the electrical operation of the system, usually in the Relay Department. In many companies the Monthly Trouble Report or its equivalent has been entitled "Monthly Relay Report" or "Monthly Protection Report" because it has been set up by protective relay installations and has been prepared by the relay engineer. In most companies, however, the report has been expanded during the last two years to cover all items affecting protection, because performance of the protective equipment has been found to be less important intrinsically than its coordination with the design and operation of the system. The Monthly Trouble Report is logically made up by the relay engineer, since the clearing of faults by protective equipment occupies the center of the stage in most cases of trouble.

To be of a maximum value in making important decisions with regard to company policy, etc., the Monthly Trouble Report must have a sound statistical basis. It is recommended that in those companies where the report has not been originated by someone with adequate training along this line, that the general procedure in compiling the report be critically examined by a statistician, with reference to the methods used in arriving at averages, etc.

Further important requirements of the Monthly Trouble Report are that it shall be sound technically, prepared with absolute fidelity to all available evidence, open minded on all possibilities in connection with the improvement of service, and vigilant in looking for such opportunities.

It is thus not accidental that someone of engineering training in one of the departments responsible for service to customers is usually sufficiently interested to initiate some kind of a report on the performance of the system during abnormal electrical conditions.

Auxiliary Records

In addition to the above fundamental report there are given herewith detailed instructions covering a typical set of daily operating records, coordinated with the above report. One of the most definite things brought out in connection with the investigation of this subject is that in revising records the next thing to do, after setting up a desired form for the results, is to coordinate the forms for the initial tabulation or description of operating events as reported by operators, load dispatchers, maintenance men, etc. Unless this is done, the derivation of the results in the form desired involves so many work

sheets and transcriptions of records as to involve much expense, delay and confusion. For this reason it is suggested that considerable attention be given to adapting daily records to their ultimate purpose.

On the assumption that most current operating events are reported by telephone, the daily log kept by the system load dispatcher (and by the division dispatchers, if any), is the initial tabulation of relaying, interruptions and miscellaneous trouble. If, however, such items are entered at random on a large log sheet, considerable delay is involved in sorting out and retabulating the various items. A better method is to divide the log sheet into sections—one section for relay operations, one for interruptions, one for miscellaneous troubles, etc. A still more promising procedure developed recently is to use separate letter size sheets for each of these records and cut down the size of the general log, as it will then contain only miscellaneous station readings, weather conditions, and other data required for permanent record but not for daily transmittal to other departments. This procedure saves copying data from the log to the relay, interruption, miscellaneous trouble and power reports. Furthermore, one day's record of relaying or interruptions may require more than one sheet of that particular form, which is easily available without using another general log sheet.

To investigate trouble efficiently, the department heads responsible should be promptly advised of its occurrence. To this end, the load dispatching office must get its daily reports out promptly. Such procedure conflicts with the requirement that certain reports customarily issued by the load dispatching office shall contain all the important evidence after a thorough investigation. These two ideas have resulted in many more or less efficient compromises as to the nature and time limit of issuing daily operating reports. Recent practice seems to favor the following procedure:

A. The load dispatcher on duty should report very important troubles immediately by telephone to the department heads interested.

B. The load dispatching office should issue a daily news bulletin to department heads and local managers covering important happenings of the day at the beginning of office hours on the following day. The information in this bulletin may be all description, or it may be preliminary tabulation on the same forms used for the official daily reports.

C. The essential results of the investigations by the department heads should be telephoned to the load dispatching office promptly.

D. Official daily reports should be issued by the load dispatching office within one to three days after their date. These will include the results of departmental investigations if essential to the reports.

To assist the dispatcher in getting all the data desired, a check list may be used. This lists the cases of trouble with a space for checking off the records affected, and also for checking their completion. One line is used for each case of trouble, thus facilitating the preparation of the analysis of trouble in the monthly trouble report, as each case may be classified as to cause.

The Load Dispatchers Daily Check List of Cases of Trouble is the only cross reference between the various daily operating reports. Many events are sufficiently well described in one report. For instance, a relay operation due to lightning may be noted only on the relay report if it results in no miscellaneous trouble and no interruptions to customers. The cases of trouble which do not cause relay operation, interruptions to customers, or damage to equipment, are very few. Such a case might

be the de-energizing of one of two parallel feeders at the request of a fire department. Such operation is abnormal and is a hazard to service supplied over the remaining feeder. The fact that such an abnormal condition could be handled without harm is important evidence as to the adequacy of the power system.

One company has been able to eliminate the use of the load dispatcher's daily check list by having a notation made on the margin of the daily news bulletin as to the cause of each case of trouble described therein.

The Load Dispatcher's Report of Miscellaneous Trouble is used only to cover occurrences which are not recorded elsewhere or are recorded elsewhere incorrectly. No form is shown for this report as it is chiefly description and not tabulation.

Some of the load dispatchers' daily reports are used only by one department or for making up monthly reports. Such daily reports would be made up by the load dispatcher on duty, inspected by the chief load dispatcher or his assistant and sent out without copying or typing.

The Load Dispatcher's Daily Report of Relay Operation is set up on a switch basis. The time the switch is closed back is shown as well as the time at which it relayed out so that it is easier to check the correctness of succeeding operations of other switches. Space is also provided for showing which target operated and the amount of ground current shown on the quick trip ammeters.

The column headed "Performance" is left blank by the load dispatcher and is filled in by the relay engineer, who makes an "OK" after each correct operation, an "X" after each incorrect operation, and a "?" after each operation which is doubtful in the light of present available information. Each questionable operation is investigated further and later is marked in accordance with the findings.

After checking over the Load Dispatcher's Daily Report of Relay Operations, the relay engineer enters the incorrect operations on a departmental record known as the Log of Incorrect Relay Operation.

The Log of Incorrect Relay Operation provides a running record of the performance of each switch, making it easy to follow the effects of changes in protection. This record uses the classification shown in connection with the Monthly Analysis of Relay Operation. A detailed explanation of the classification of incorrect relay operation is given in the next section headed "Definitions."

The Daily Report of Interruptions Affecting Customers is intended for distribution to the Commercial Departments interested in service to customers as well as to the Technical Departments.

In the typical form herewith, the Daily Report of Interruptions Affecting Customers is set up in two sections. The first is a tabulation which shows at a glance the important interruptions. The second is a brief general description of the reason for the interruption, stated in such language that it is clear to the commercial men and others responsible for explaining the interruption to the customers.

The Load Dispatcher's Daily Report of Kilowatt-Minutes Lost is a tabulation of kilowatt-minutes of interruption allocated against primary substations and high tension customers. It is computed by the load dispatcher on duty (so that sufficient information will be obtained immediately), checked the next day and sent to the relay engineer who notes in each column the cause of the interruption. Only one column is used for each interruption regardless of the number of stations affected and of the number of separate interruptions as long as they were due to one original cause. This report is filed until it is time to make up the Monthly Trouble Report. At this time the sheets are summarized horizontally by stations and classified as to Division and Cause. The classification as to Division is used chiefly for segregating generation and transmission interruptions from distribution and utilization interruptions.

This kilowatt-minute report takes the place of several reports otherwise desirable as it provides a tabulation of all interruptions to customers classified by substation, time, origin and cause, with a weighted measure of each interruption. The horizontal summary gives results directly in kilowatt-minutes. These are divided by the respective substation loads in kilowatts to get the total minutes of interruption to the average customer supplied from each station. The number of complete interruptions and of partial interruptions is best summarized from the Daily Report of Interruptions Affecting Customers.

Definitions

In classifying and tabulating operating events, questions often arise which are difficult to answer logically, but it is not so important to adopt a logical classification as it is to adopt one that will be accepted and followed uniformly. As a matter of interest in this connection, the interpretations and decisions of several operating companies are given below. These definitions apply chiefly to the Relay Analysis section of the Monthly Trouble Report. While these may not be satisfactory for general adoption, they are suggested as subjects for discussion in arriving at standard practices.

"Defective Equipment" includes defects in protective equipment, including relays, auxiliary relays, battery supply, control wiring, auxiliary switches, trip coils, instrument transformers, fuses, tripping reactors, etc. It is intended to cover defects in an individual piece of equipment rather than undesirable characteristics common to a class of equipment which should be known and considered in system planning and system design.

"Personnel Failure" is intended to cover mistakes by field relay men, construction men, operators, etc., which prevent the proper operation of protective equipment, or which cause the operation of protective equipment when there is no fault to be cleared by its operation. This classification includes only those mistakes which are a liability of the protective equipment. Mistakes in connection with other equipment which require breaker operation to clear the resulting trouble are not considered as involving incorrect protective equipment operation. "Personnel

TABLE XIII

DAILY REPORT OF INTERRUPTIONS AFFECTING CUSTOMERS

Day: Wednesday. Date: January 9, 1929.

Weather: Cloudy with wind and rain.

Customers Affected	Average Kw.	Total Minutes	Times Interrupted	Origin (Division)
Disturbances				
Hartsville Line..................	45	1	1	S.W.
Carter St.-Ridgedale No. 2 feeder..	2700	1	1	Chatt.
Clearances				
Warioto Cotton Mill feeder.......	2200	17	1	Nash.
Niota Substation................	10	38	1	P. & T.

At 9:55 a.m. service to the Hartsville line was interrupted for one-fourth minute when the oil switch controlling this line at Carthage Substation opened by overload relay due to a highway crew blasting near this line.

At 12:02 a.m. service to the Warioto cotton mill feeder was interrupted for 17 minutes by appointment when this line was cleared in order to replace a pin in a crossarm between Second and Third Avenues on Jefferson Street.

At 11:55 a.m. service to the Carter Street-Ridgedale No. 2 tie line was interrupted for one minute when the oil switch controlling this feeder at Carter Street Substation opened by ground relay due to trouble at the Cotton Compress Company.

At 12:00 noon service to Niota Substation was interrupted by appointment for 38 minutes when the Athens-Sweetwater section of 66 kv. line was cleared in order to tighten lugs on the west air-break switch at Sweetwater.

Failure" does not cover poor engineering judgment. It does include careless or intentional violation of instructions, misreading of data, typographical errors, poor manipulation of tools or material, mistakes in wiring and other such mistakes as are clearly assignable to a particular person and not to a defective piece of equipment or to poor engineering judgment in the application and operation of equipment.

"Relay Engineering" includes incorrect operations due to causes within the control of the relay engineer, on the assumption that the relay engineer has a free hand in specifying type, rating, connection, setting, testing, etc., of relays.

"System Inadequacy" includes incorrect operations due to causes beyond the control of the relay engineer, not due to a particular person, or to a defective piece of equipment, but due to a lack of, or misapplication of, equipment or methods. It covers all cases of incorrect operation not due to defective equipment, personnel failure, or relay engineering, considering as incorrect each case where there is proved economic justification for improved facilities to reduce interruption or damage. "System Inadequacy" includes incorrect operations due to poor system planning, poor detail designing, poor operating methods, lack of equipment, defects common to a class of equipment, misapplication of equipment, poor coordination of the various elements in an installation, etc.

One of the most difficult things to arrive at is an adequate definition of "Correct" system operation. This report is based on the following definition:

> To perform correctly, the system, including equipment, personnel and routine, must clear up an abnormal condition

with less damage and interruption than any other economically justifiable system.

The procedure required to "prove" economic justification for improved facilities may vary with different companies. In balancing the cost against the value of the improved facilities, the relay engineer usually is the person best acquainted with the extent of the interruption and amount of the damage, as well as with the changes in facilities or methods required to reduce interruption and damage, but he may not be able alone to estimate the cost of such changes. However, in all companies some qualified individual analyzes certain trouble and suggests remedies. This report recommends that in such a technical field as electrical operation the relay engineer be the party authorized to recommend such changes as he may consider economically justifiable, and to consider as incorrect such operations as presumably would not have occurred if the recommended changes had been in effect. It is further recommended that the relay engineer attempt economic justification of improved facilities only after a thorough investigation of the operation in question and after consultation with the other department heads familiar with the proposed improved facilities. He should obtain their advice but not necessarily their consent, as the responsibility for reducing interruptions and protecting equipment is logically his.

Many other definitions of correct relay operation have been used at various times. Most of these are listed below, each followed by a statement of its shortcomings as they are seen from the standpoint of this report:

"Relay Operation is correct if the equipment acts as the relay engineer expects it to act." Then it would always be correct if the relay engineer knew enough about his equipment and the laws of nature to predict its performance under any condition.

"Relay Operation is correct if it makes the best possible use of existing equipment." It is the duty of the relay engineer not only to make the best use of what he has, but also to get what he needs. To consider "whatever is, is right," is to stand in the way of advances in the art, as well as to prevent accepting the best standards of present practice.

"Relay Operation is designed for certain frequent operating set-ups. Unusual set-ups will unavoidably interfere with relay operation, which should, nevertheless, be considered as correct, if operation is correct under the designed conditions." There ought to be some way of measuring the adequacy of the design of a relay system in meeting unusual as well as normal conditions. Otherwise we place a premium on ignorance of the requirements of profitable operation. To consider unsatisfactory operations as correct if they occurred under conditions not anticipated does not tend to develop more adequate relay systems or to discourage operating set-ups which are difficult to relay. To consider such relay operation as incorrect does direct attention to an unsatisfactory condition and tend toward its betterment if an economically justifiable solution can be found—and it usually can.

"Relay Operation is correct if the best present day protective equipment and relay schemes are properly applied, even if in the present stage of the art insufficient protection is provided under certain operating conditions." Even if the art of relaying has reached a high state, it is likely that economically justifiable changes in operating methods may be made or that proper system planning could have eliminated those conditions that overtax the best relay schemes. Experience shows that present relay equipment and relay schemes are adequate to give 100 per cent protection under all justifiable operating conditions if protection is adequately considered in system planning.

"Relay Operation is incorrect if undesired." Correct operation must be attainable in the present state of the art, otherwise incorrect operation is a justifiable condition. If there is no known way of improving relay operation, it is correct.

"Relay Operation is correct if it makes the best use of such breakers as are automatic and of sufficient capacity to clear the trouble." If there were an established practice of periodically reporting the deficiencies in major equipment applications and performance, protective equipment reports might be confined to relays and their accessories. However, relay operation reports are customarily depended upon for their story of the performance of the system during abnormal conditions. In the absence of any particular objections to this practice and in view of its established position, we see no reason for limiting the scope of relay operation to minor or control equipment.

Special definitions with regard to relay operation are shown below:

1. Operation of relays by hand or electrically for test are included in the Daily Report of Relay Operations, but are not counted in the monthly summary, whether correct or not.
2. Do not count fuse failures in the monthly relay analysis. They may be included in the daily report if desired.
3. Classify incorrect operation of relays due to poor adjustments as due to incorrect settings.
4. In the relay report do not count auxiliary relay operations which do not interrupt fault current. For instance, an auxiliary relay may trip the low side of a transformer whenever the high side opens, to facilitate paralleling, but the low side operation should not be counted unless there is a source of power on the low side.
5. Interruptions to tie lines may be considered as by appointment after communication with the other company's dispatcher and securing permission to leave the tie line open.
6. If one breaker fails to open and a second breaker has to open to clear the trouble, consider the first operation as incorrect and the second as correct.
7. When a line supplied from an ungrounded system gets down on the ground or other non-insulating material, charge up an incorrect operation due to lack of grounding transformers.
8. Consider the incorrect operation of a potential operated relay due to potential fuse failure as a liability of this type of relay, and classify it as a miscellaneous relay trouble on the assumption that the type of relay is correct.
9. Count one relay operation for each switch operation regardless of the number of relays which tripped the switch.
10. Consider failures to relay on out-of-step conditions within a plant or between plants as incorrect under the head of Poor System Planning, since there are at present no adequate relays for out-of-step conditions, and the only apparent remedy lies in improving the excitation system.
11. If a flashover burns the current transformer or trip circuit open, do not charge up an incorrect operation, whether the breaker opens or not.
12. If lightning trips out a switch by grounding the control cable, consider the relay operation as incorrect unless there is no economically justifiable means available for preventing a repetition of the trouble.
13. If a load dispatcher tests a bad line in series with a good line when he could have tested the line direct from a generating plant with a reduced interruption, consider the relay operation on the good line as incorrect and due to poor operating practices. If there are specific instructions against this practice,

however, consider the operation as incorrect and due to personnel failure on the part of the load dispatcher.

14. If the system is operating with one of two parallel lines out of service unnecessarily and additional switches open due to a back-up protection for single line operation, this operation should be classified as incorrect and due to poor operating practices.

15. If circuits trip out due to additional load being added without notice, charge this up as incorrect and due to poor construction practices.

16. Charge up incorrect operations in connection with the experimental setting of relays under the classification "RX."

17. Do not count as a relay operation a switch opening due to control wiring trouble if trip current does not pass through the relay.

18. In general, any urgent hand operation of a breaker to clear trouble is incorrect.

19. In general, any relay operation is correct if there is no known justifiable way of improving its performance.

20. If a station does not have bus protection, the clearing during station trouble, at either or both ends of lines which supply the station is considered as correct.

21. In classifying interruptions by divisions of a company, the operating jurisdiction of the Division is used.

22. Do not use the classification "Unknown" or "Miscellaneous" unless absolutely necessary. The entire classification is a matter of judgment, and it is better for the man responsible for the report to make a guess at the time of the trouble as to the classification than to accumulate a large number of "Miscellaneous" and "Unknown" items which cannot be analyzed even approximately at a later date by someone less familiar with the details.

23. Do not count cases where a customer closes a relay accidentally.

24. Do not count customer's relay trouble in the relay report unless the customer's relay engineering is done by the power company.

25. Consider switch operation by hand on account of overload as incorrect if the overload is such as could have been carried for a few minutes or until the operator could call the dispatcher, providing also that there were no relays which should have operated at this overload.

26. If a generator winding breaks down between turns but does not take sufficient current to operate properly set differential relays, do not count any relay operation, since there is at present no known way of clearing minor coil failures between turns.

27. In general, all switching done under the jurisdiction of the dispatcher to reduce overload is correct, as it is not intended that all system switching should be performed by relays. The relays are intended to take care of things which cannot wait for the dispatcher.

28. Do not charge an incorrect operation due to obsolete relays as due to the wrong type of relay. Charge up an incorrect operation due to poor detail engineering design.

29. Charge up insufficient grounding capacity at stations to system planning, the same as a lack of any grounding transformers.

30. Consider loss of load due to clearances during stormy weather as incorrect and due to poor operating practices.

31. In case a switch comes out by differential relay and the operator forgets to reset the auxiliary relay, causing the switch to relay again when he attempts to close it, do not count this last operation as a relay operation, as it is not concerned with the clearing of trouble.

32. Whenever there is any question as to whether an interruption was due to weather conditions or some other cause, charge it to weather conditions.

33. Whenever there is any question as to whether an interruption was due to defective equipment or system inadequacy, use the classification "System Inadequacy."

34. Momentary interruptions to lines are not classified as equipment failures, but permanent interruptions are so considered unless there are extenuating weather conditions.

35. A lighting flashover on a transmission line should be considered as legitimate, but a bus flashover should be considered as illegitimate and probably due to system inadequacy in connection with lightning arresters.

36. Normal replacements and adjustments should not be counted as cases of trouble if the work is prearranged and if there is no interruption or only an interruption by appointment.

37. To operate correctly, protective equipment must isolate a maintained fault with less interruption and damage than any other economically justifiable installation.

THE USE OF HYDRO-ELECTRIC UNITS AS SYNCHRONOUS CONDENSERS[1]

Foreword

The use of hydro-electric units as synchronous condensers is coming to be an accepted practice in the field of hydro-electric development. This practice, like so many other electrical problems, is the direct result of the ever-increasing demand for better voltage, better power factor, and for better service conditions. All public utility concerns now recognize the necessity of operating their systems in such a way as to meet this ever-increasing demand.

This paper records the general experimental results and economic conclusions of a number of operating companies who have equipped their hydro-plants so the units can be used as synchronous condensers.

In this report, hydro plants have been classified as either run of river or storage plants. By run of river plant is meant a plant whose operation is governed entirely by river flow conditions and which at the most can store only a limited amount of water during the week-end light-load period. Storage plants have enough storage capacity for seasonal river flow regulation with only one major fill-up and draw-down per year.

The kilowatt-hour storage figures given are based on the economical draw-down, and represents the generation from the passage of the stored water not only through the storage plant but also through all plants on the same stream below the storage plant.

Typical Installations

One company has recently equipped six of its small hydro plants to be used in this way as synchronous condensers. As the efforts of this company are typical they will be described in detail. These plants are all on streams that have a low water season each fall. Most of these plants were recently acquired in the taking over of three small power systems serving a very promising lighting and factory territory. They all feed into a comparatively low voltage network. Constantly increasing load, lagging power factor and the urgent need of voltage boosting (under the low water conditions of no kilowatt-hour output) resulted in trying out the synchronous condenser idea.

Preliminary consideration brought out three essential problems:

1. To maintain an unfailing water supply to all lignum vitæ bearings.
2. To eliminate water from wheel chambers to minimize power losses.
3. To determine the operating characteristics of the water wheel unit used as a synchronous condenser and determine if satisfactory operation could be expected if the necessary changes were made in the hydraulic end.

The time and expense of equipping any one of these plants for use as a synchronous condenser was relatively small, but it was not always known just what the behavior of an ordinary generator would be if the water was cut off, and the generator allowed to motor continuously.

Let us consider the first and second problems together. Five of a group of six plants converted were of the open-flume type, which entirely sealed the draft chest and prevented the draft tube from emptying. In the vertical type units there were no lignum vitæ bearings to become unwatered when the draft chest and runner space were empty. In this case it was only necessary to provide an effective means of allowing the water to pass out of the water-wheel when the turbine gates were entirely closed and the unit still on the line. The first scheme tried was that of putting a two-inch pipe opening through the cover-plate, just over the runner, this pipe being controlled by a suitably placed valve on the operating floor. It was found that when the gates were closed and the valve opened the water-wheel would not always evacuate. As all the vertical type plants had been so built that it was possible to insert a 3-inch pipe through the concrete into the draft tube, just beneath the runner, this was tried out. In all cases where the runner had been placed so that the pipe was never below high tail water the water-wheel would always evacuate.

In the case of the horizontal units there were saddle bearings in the middle of the draft chest that had to have an auxiliary water supply when the unit was used as a synchronous condenser. A screened supply of water from the open flume was piped through the draft chest manhole cover directly into this lignum vitæ saddle bearing. A 3-inch pipe directly into the draft chest brought up to the top of the pit with a throttle on the pipe successfully controlled the air inlet. A cone-shaped valve and seat placed inside the screen on the manhole cover just above the saddle bearing was interlocked by a system of inclosed rods and levers to the main air throttle in such a way that when the unit was being used as a synchronous condenser, the opening of the air throttle opened the water supply and vice versa.

The third problem referred to, or the behavior of the generators under such conditions, was the most vital. All of the eleven generators experimented with were made by reputable manufacturers. It was found that in eight instances the generators of one make would operate with entire satisfaction at a plant located near the center of distribution, while in three instances a generator of the same make, size, and with practically the same speed would not work satisfactorily at the end of a relatively long line when carrying either partial or full boost kilovolt amperes. Pulsations would invariably set up, and no adjustment of voltage on either exciter or generator field would damp out the oscillations. The use of these three generators as synchronous condensers was temporarily abandoned.

---

Publication No. 289-66, Serial Report, Hydraulic Power Committee.

Horizontal Units More Satisfactory

Of the group of six plants converted, four have vertical and two horizontal units. It is interesting to note in this connection that all of the plants that did not operate satisfactorily were of the vertical type, while plants of the horizontal type have given no trouble at all.

In testing out units, operated as synchronous condensers, without evacuation of wheel chambers, it was found that with gates closed each unit would draw about 20 to 30 per cent of its rating from the line. When the water-wheel was allowed to evacuate, the unit would draw from 4 to 7 per cent of its rating. One low head unit drew 9 per cent. The tests showed that in the cases cited it took from four to six times as much power to operate the units as condensers with wheel chambers full of water as it did when wheel chambers are empty. It was also noted that as long as the water was allowed to remain in the wheel chambers of the three unstable machines used as synchronous condensers, discussed above, no difficulties due to pulsations of voltage and current ever occurred. Unwatering the wheels made the resulting synchronous condenser unstable.

Turbines equipped with automatic vacuum breakers will, of course, automatically empty their draft tubes whenever the machine is operated with gates closed, as would be the case when used as synchronous condensers.

Attention has recently been called to the fact that the admission of air through openings in the head cover results in a distinct improvement in efficiency of turbines at low gate openings. Such openings are controlled automatically by the governor and, of course, operate to break the vacuum when the gates are closed. These devices, therefore, serve a double purpose when the machine is also used as a synchronous condenser.

Proper lubrication of the main turbine bearing is essential. Where runner clearances are small, as in high head practice, a small quantity of water may also have to be supplied for the purpose of minimizing the possibility of heating in case of slight rubbing contact.

If possible, it is desirable to provide some means of determining and checking runner clearances, when it is planned to motor the unit as a synchronous condenser, so that injurious rubbing contact may be avoided or corrected. Clearances or wobbling can be measured or checked by means of a stationary bracket, or pointer, attached to the turbine head cover or guide bearing. The distance between it and the shaft can be measured with a pair of inside calipers, and the amount of wobble measured or checked. By using two brackets, having adjustable cap screws and lock nuts, each set and locked at a given distance from the shaft, when the clearance is uniform, any variations may be detected, measured and adjusted for.

Turbine runners are often set very nearly down to tail-water level. Under such conditions large runners are apt to lift the tail-water level to such an extent as to cause a large amount of undesirable frictional resistance between the runners and the water. In such cases, forcing compressed air into the tailrace may have to be resorted to in order to force the water in the draft tube to a proper distance below the runner.

It is not the intent here to go into a discussion of the theoretical phases of this subject. That would furnish ample material for a separate paper. However, it seems that the following points should be mentioned: Two of these machines that would not operate satisfactorily at the end of a small conductor, low voltage line are duplicates of two other machines which do operate satisfactorily at a center of distribution. This indicates that the characteristics of these machines when combined with the characteristics of the small conductor, low voltage line, produce an unstable condition. Again, a part of this trouble may be due, not so much to the line conditions as it is to the reactance of the group of generating stations against the reactance of the unit being operated as a condenser. Knowing the characteristics of the generator to be operated as a synchronous condenser, and calculating the characteristics of the line to which it is connected, the probable results could be quite accurately forecast. Again this brings up the stability limit of a system composed of generators or condensers or both, and it is probably true that under certain load conditions on these high resistance lines there is not enough synchronizing power left to hold the units in step when being operated as synchronous condensers.

This company, in taking up the matter with the manufacturers, found that the cost of new field poles for these three machines (which would include amortisseur windings) was not at all prohibitive. The cost of building new lines for higher voltage or larger conductor was prohibitive.

However, as the eight generators which are operating satisfactorily as synchronous condensers are at present taking care of voltages and power factor requirements under low water conditions without the use of the three unstable machines, there is no need at present of making alterations. It is believed that these three units could be utilized if the proper additions are made.

As to the cost of equipping old plants to be operated as synchronous condensers, it seems that there are very few instances in which this could not be done economically.

If satisfactory regulation, under low water conditions, is an essential, then the expense of installing new field coils, including amortisseur windings, is certainly permissible. In the cases cited, and in many similar cases, the use of the generators as synchronous condensers brings about the desired results at only a fraction of the cost of separate synchronous condenser outfits, and utilizes equipment which would otherwise be idle.

New Plants Installed

As a result of the experiments with these small generators, the company referred to has equipped each of its three units in a new 63,000 kw. hydro-electric station with vacuum break pipes. This consists of a six-inch pipe entering the draft tube just beneath the lowest point of the vertical runner. This pipe is brought around the scroll case, and up some twenty feet to a valve on the operating floor. Provision is also made for letting compressed air into this vacuum pipe to hold elevation of tail-water below water-wheels if desirable during high tail-water.

One of the 21,000-kw. machines in the new plant is equipped with amortisseur windings at an additional cost of $1,400. The governor is set so that when operating as a synchronous condenser it will quickly pick up the load that might be suddenly thrown on, and take up the regulation of the speed. Thus, with a water storage of 3,000,000 kw-hr. back of it, this 21,000-kw. machine serves at one and the same time as a synchronous condenser to boost voltage during low water periods; to buck voltage during light load periods and as an emergency energy stand-by unit within the limits of the water storage. The increased generation can be added automatically when needed by the operation of the governor.

The superintendent of power control of a large interconnected system calls attention to the fact that the use of hydro-electric units as synchronous condensers greatly improves the operation of the system relaying, inasmuch as it provides synchronous capacity at hydro stations during off-peak and low water periods.

When hydro units are being run as condensers, with head gates open and guide vanes held closed by proper governor setting, the units are available for use as standby capacity, if the frequency falls below a predetermined value.

Geographic location of hydro plants, with relation to load centers is also a factor which should be considered in connection with a plan to use them for this purpose. Unless financial or other special conditions forbid, it may be found more economical to install synchronous condensers in locations near the large load centers.

Questionnaire Basis of Study

As a basis of this study, the following questionnaire was sent to all southern hydro-electric companies, who indicated that they were using their generators as synchronous condensers:

1. Number of generators—horizontal or vertical —reaction or impulse.
2. Full load kw-hr. rating each.
3. Generator voltage.
4. R.p.m.
5. How are generators excited?
6. Transmission line voltage.
7. How many generators used as synchronous condensers and approximate cost of equipping them for use as such?
8. Kw. required to operate as synchronous condensers.
9. How do you secure evacuation of water from wheel and draft chambers?
10. How are exposed water-wheel bearings, if any, cared for?
11. Relative location of plant as to load (end of long line, center of distribution, etc.).
12. Does generator have amortisseur or damper field windings? If no damper windings now, do you contemplate installing them in the near future? Give proposed cost of such installation.
13. Does generator have greater tendency to go out of phase when used as synchronous condenser?
14. Approximate change in voltage and power factor when using full effect of condenser.
15. State your opinion as to the merits of this method of voltage and power factor regulation.

Replies were received from about 25 stations. The tabulation of the replies (see Tables I to V inclusive) show that at least 80 per cent of the southern hydro-electric companies (and many companies in other parts of the country as well) use their generators in some form as synchronous condensers.

A few of the replies show that some operators may not be aware of the excessive loss of water which occurs when floating a generator on the line, or the excessive loss of energy which occurs with gates closed and unit operated with wheel chamber full of water as compared with the small percentage of energy required from the system to operate the generators as synchronous condensers with water-wheels running in free air. The reduction in running losses by removal of the water from the wheel chambers can be directly evaluated in dollars and represents a saving of considerable magnitude.

Another point brought out is the fact that these water-wheel synchronous condensers fall out of step much more easily when bucking voltage than they do when boosting. This agrees with the operation of a regular synchronous condenser, as would be expected.

One plant reported that the idea of evacuating the wheel chamber was investigated, but was not found practicable because of the fact that the fore bay was almost entirely filled with silt, and at practically any time of the year the water will begin spilling over the dam if it is shut off at the turbines for 20 or 30 minutes; consequently there was nothing gained in shutting the water off the wheel.

Two plants reported that such alterations were not advisable in view of the fact that the plants would soon be rebuilt. One plant reported that they would soon change from manual to automatic operation.

One company reports the use of a double-decked generator. It has a 60-cycle, 25,000-kw. generator mounted on top of a 36-cycle, 17,000-kw. generator, both connected to one 27,000-h.p. water-wheel. By this means they deliver power to either of two large power consumers, one a local 36-cycle system and the other a 110,000-volt, 60-cycle transmission line. The 60-cycle machine is equipped with amortisseur windings, and provision is made to empty the wheel chamber when operated as a frequency changer to take power from the 60-cycle system for use on the 36-cycle side, when water is scarce.

Two units report 100 per cent variation in power taken from system, depending on kv-a. loading. A check on this estimate would no doubt reveal a fairly constant kw. taken from system practically independent of kv-a. loading.

There was no opportunity to discuss the replies to the questionnaire with each contributor. They are tabulated just as sent in. It would be very interesting and instructive to have a record of actual test runs on all the apparatus referred to in the five charts shown. There can be no doubt but that such a record would show up much more information favorable to the use of hydro-electric units as synchronous condensers. A regular synchronous condenser of 1000 kv-a. capacity would probably cost around $14,000, including shelter. This would represent an annual charge of about $2,000.

In many cases the use of generating units as synchronous condensers, steam as well as hydro, entirely avoids this heavy annual charge at practically no additional expense and utilizes machinery that would otherwise be standing idle.

A large system in the Northwest reports a saving of between 2 and 3 per cent in efficiency by motoring one unit in a large plant, as a synchronous condenser, and running the other units at their points of greatest efficiency.

Another large hydro power company reports that the venting of draft tubes reduced the power required to motor a 21,000-kw. unit, from 5000 kw. to 500 kw., and for a 9000-kw. unit, from 1500 kw. to 200 kw.

A study of the charts will reveal other interesting and helpful information.

MECHANICAL RELIABILITY OF HYDRO-ELECTRIC UNITS—1927

The present report embodies the results of the fourth year's study of this subject by the Hydraulic Power Committee. The same restrictions upon age and size of units were continued from the earlier years, namely, installation in 1920 or later and a capacity of 5000 kw. or greater.

The fact that for 1927 records were contributed for 134 units, as compared with 95 in the 1926 report, indicates the very encouraging increase in cooperation which has been noted of member companies operating eligible units from year to year. The units reported upon this year include 91 of the 95 in the 1926 report, 14 of which were installed during 1927 and 29 of earlier date than 1927, but for which no data had been previously contributed.

In the collection, tabulation and analysis of the data, no change has been made from the previous year's procedure. Also a complete definition and description of all the terms used having been made a part of the first report in 1924, it is believed unnecessary to repeat these. The 1927 records were contributed by 31 operating companies.

Of the 134 turbines, 106 were of the vertical reaction type (non-propeller) with a total rating of 2,572,780 h.p.; 9 of the horizontal reaction type (total rating 142,400 h.p.); 11 of the impulse type (total rating 274,000 h.p.); and 8 of the propeller type (232,000 h.p.), making a grand total of 3,221,180 h.p. and an average rating of 24,039 h.p. Combined with these turbines were 114 vertical generators, having a total rating of 2,031,260 kw., and 20 horizontal generators, with a total rating of 288,450 kw.—grand total, 2,319,710 kw.

The range of the generator ratings is from 5000 to 52,000 kw., with an average of 17,311 kw.; that of the speeds from 90 to 600 r.p.m.; and that of the heads from 45 to 2381 ft. The range of head of reaction type units is from 40 to 909 ft.; while the impulse type units extend from 1108 to 2381 ft.

Table I lists the principal characteristics, by reference groups, of all of the units whose analysis has been included in this report. The operating records for the year 1927 are tabulated by reference groups in Table II. In Table III the records of the units of each type are summarized and compared with the corresponding summaries for 1924, 1925 and 1926 and with a summary of steam unit reliability records for the year 1925, taken from a Serial Report of the Prime Movers Committee on Turbines, N. E. L. A. Pub. No. 267-78.

The range of outage time percentages for 1927, as noted in Table II, except for one unit which is far out of line, are quite comparable with those of previous years, namely, from 14.77 per cent to 0 for the total outage time; and for the outage time in demand, 14.59 per cent to 0. The extremely high outage time percentages of the one unit mentioned are due principally to the reduced base upon which they are computed, this unit having been installed late in 1927. Of the 80 reference groups, 31 are noted as having 0 outage time in demand.

Fig. 1 shows the outage time, both total and in demand, of all the reference groups arranged by type of unit, and also in the order of decreasing magnitude of total outage time.

The outage time percentages, both total and in demand, have been plotted for each individual unit in Fig. 2 against the year of installation. Neither installation nor least squares analysis of the data indicated any relation between age and outage time of magnitude comparable with the division of the individual units from the average. This result provides further confirmation of the conclusions reached from study of the earlier data on this relation.

Table IV contains the outage time percentages averaged according to year of installation for the years 1924, 1925, 1926 and 1927.

Fig. 3 is derived by entering the outage time percentages of each reference group against the generator rating. Again, no definite relation is observable between outage time, either total or in demand, and the size of the unit.

Table V presents an analysis in total by reference groups and causes of outage of the total outage hours; these details being summarized into classes according to turbine type with the per cent of the total outage time resulting from each case in Table VI.

For all of the classes of units in Table VI, the most important principal group of causes of outage time is Waterwheels and Auxiliaries. The next in order is Generators and Appurtenances, and the last, General Hydraulic Causes.

Of the individual causes affecting the outage of the entire number of units, Headgates or Intake is the largest item of General Hydraulic Causes, with Other General Hydraulic Causes following. In the Water Wheels and Auxiliaries group the leading place goes to the Runner, with General Overhauling and Replacements second. Cleaning and Other Causes respectively hold first and second places in the group of Generators and Appurtenances.

Publication No. 289-68, Serial Report, Hydraulic Power Committee.

TABLE I

PRINCIPAL CHARACTERISTICS OF HYDRO-ELECTRIC UNITS, 1927 DATA

PENSTOCK VALVES

Introductory

The purpose of this report is to give a brief review of current practice in the use of valves in penstocks. The investigation of the committee has been limited to the types of valves which are usually located in a closed penstock or conduit leading from an open forebay or surge chamber to the hydraulic power units of a water power plant. This definition excludes governor or pressure operated relief valves, head gates for the control of diversion from reservoirs and streams, and free discharge valves, although certain of the types considered are applicable to these uses.

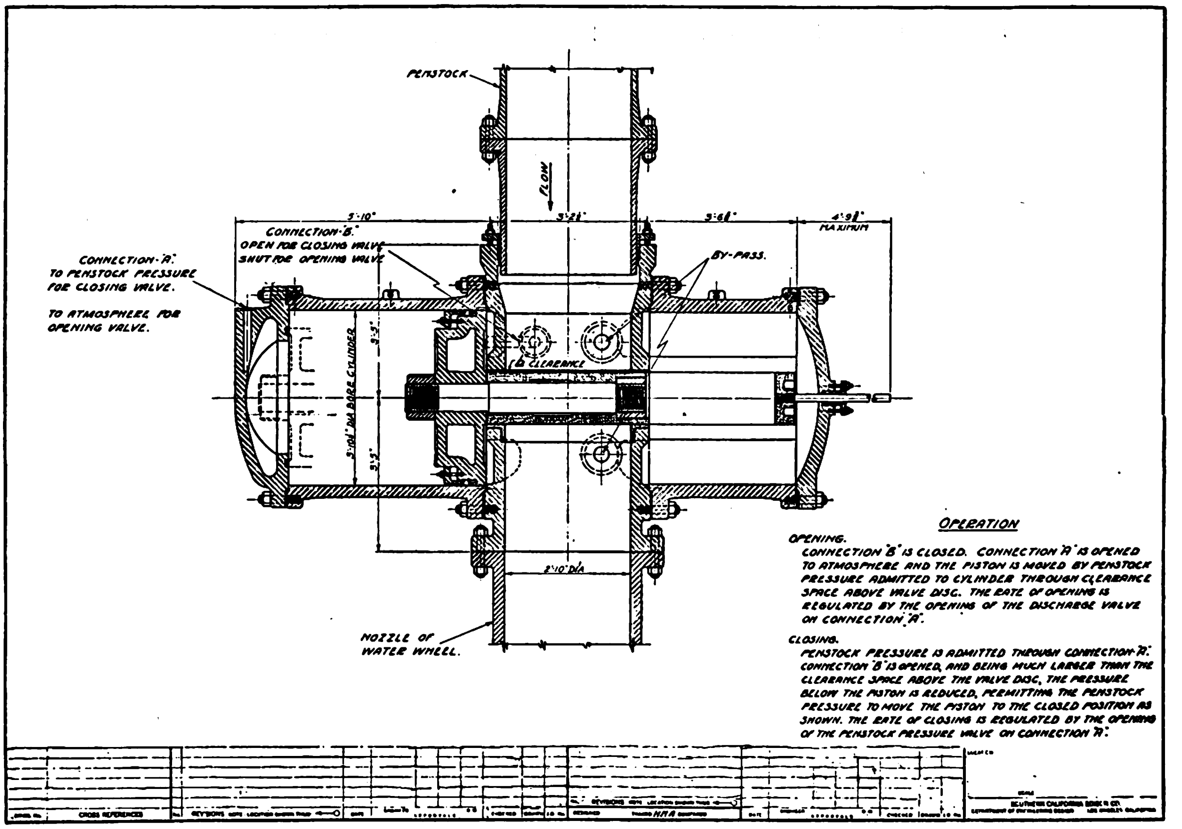
The material in this report has been compiled from data submitted by the Pacific Gas & Electric Company, the San Joaquin Light & Power Corporation, the Southern California Edison Company, the Portland Electric Power Company, the Western States Gas & Electric Company, the Niagara Falls Power Company, the New England Power Company and the manufacturers whose statements appear at the end of the report.

Location of Penstock Valves

In general, and always in high head installations, there are at least two valves located in a penstock line; one at the upper end as near as possible to the surge chamber or forebay, and another just above the hydraulic power unit. The object of the upper valve is to shut off the water from the penstock in order to drain it for repairs or inspection, or in case of a break in the penstock. The object of the lower valve is to permit inspection of the hydraulic power unit without draining the penstock, and in case of accident to the power unit, to shut off the water more quickly than could be done with the upper valve. In case a power unit is to be shut down for a considerable time, but must be kept in readiness for operation, a valve just above the unit will prevent leakage through the turbine gates which might cause rapid wear.

In low and medium head installations but one valve is quite common and that one located at the penstock inlet. With the lower heads, the penstock is generally correspondingly shorter, and one means of control is adequate.

Valves are always located in interconnections between penstocks, and in the case of a single penstock branching to serve more than one unit, valves should be located in each branch, near the junction, so that trouble with one unit will not make it necessary to shut down the other units. In very long penstock lines, valves at intermediate points might be used to sectionalize the lines in case of a break.



OPERATION

OPENING.
CONNECTION "B" IS CLOSED. CONNECTION "A" IS OPENED TO ATMOSPHERE AND THE PISTON IS MOVED BY PENSTOCK PRESSURE ADMITTED TO CYLINDER THROUGH CLEARANCE SPACE ABOVE VALVE DISC. THE RATE OF OPENING IS REGULATED BY THE OPENING OF THE DISCHARGE VALVE ON CONNECTION "A".

CLOSING.
PENSTOCK PRESSURE IS ADMITTED THROUGH CONNECTION "A". CONNECTION "B" IS OPENED, AND BEING MUCH LARGER THAN THE CLEARANCE SPACE ABOVE THE VALVE DISC, THE PRESSURE BELOW THE PISTON IS REDUCED, PERMITTING THE PENSTOCK PRESSURE TO MOVE THE PISTON TO THE CLOSED POSITION AS SHOWN. THE RATE OF CLOSING IS REGULATED BY THE OPENING OF THE PENSTOCK PRESSURE VALVE ON CONNECTION "A".

FIG. 1-A.

Publication No. 289-72, Serial Report, Hydraulic Power Committee.

Choice of Type of Valve

Penstock valves are never operated at part opening. They are always either fully open or shut. For this reason the hydraulic characteristics of the valve at part opening are of no importance, except for the effect that they may have on the smoothness of operation and on the wear of the valve parts during the period of closing or opening. Such valves are rarely operated under flow conditions. They should be designed to give good hydraulic condition at full opening and to be structurally strong enough not to be damaged in any way by the disturbances due to throttling when they are opened or closed with unequal pressures above and below.

The valves reported on cover a wide range of types, sizes and operating conditions.

Gate valves are in use at both the upper and lower ends of penstocks, and in the high head plants of California they are the predominant type. Gate valves 96 in. in diameter are used at the upper end of one plant and operate satisfactorily at a head of about 70 ft. One plant is using 32-in. gate valves of the follower ring type at the bottom of the penstock under a head of 2381 ft. Gate valves of the follower ring type 24 in. in diameter have been in successful use for more than ten years under a head of 2100 ft.

A recent design of hydraulically operated gate valve, for which a patent has been issued, is illustrated in Fig. 1A. Four of these valves have been installed for a head of 2400 ft., and are operating satisfactorily. Some of the advantages of this valve are: (1) A considerable saving in weight and cost over a comparable gate valve of the usual design; (2) a saving in space requirements; (3) elimination of stuffing boxes, except for the indicator rod.

Butterfly valves are also used quite extensively both at the upper and lower ends of penstocks.

Butterfly valves at the upper ends of penstocks have been installed with diameters of 11 ft. 6 in. for a head of 140 ft., and 7 ft. 6 in. for a head of 230 ft. These valves have cast steel disks and bodies. Structural steel valves 27 ft. in diameter have been installed in an Eastern plant for about 90 ft. head.

At the lower ends of penstocks, butterfly valves 9 ft. inside diameter are operating under a head of 455 ft., and a 72-in. valve has been operating for over three years under a head of 930 ft. This is the highest head for any butterfly valve ever used, as far as the committee can ascertain.

Manufacturers of butterfly valves state that there is no apparent reason why such valves cannot be built to operate successfully at heads of 1000 ft. or more.

Needle valves, unbalanced and externally controlled, have been used for many years for the highest heads at which water power has been developed. These valves are regulating valves directly controlling the jets of impulse wheels, and do not properly come within the scope of this report. Moreover, they are of comparatively small size, the largest being about 11 in. diameter, but the maximum operating velocity is very high, as high as 300 ft. per second or more. These valves are mentioned because there is no question as to their reliability, although they are subject to rather rapid wear, and consequent leakage, due to the high velocity and their constant operation at full and partial opening.

In one California plant, unbalanced needle valves with external hydraulic cylinder control are used as penstock valves just above the needle nozzles of the power unit.

Balanced plunger valves have been used as shut-off valves adjacent to the power units in a number of California plants. Johnson valves with internal hydraulic control 72 in. diameter, under 830 ft. head have been used. In these valves the pressure in the internal hydraulic operating chamber is controlled by a system of external needle valves. Johnson valves with a mechanical control of the internal pressure chambers are in use in sizes up to 24 in. diameter under 2100 ft. head.

Johnson valves 21 ft. in diameter, under 200 ft. head, are in operation in the plant of the Niagara Falls Power Company.

In general, insofar as the head under which the valve is to operate affects the choice of type, both gate valves and balanced plunger valves are in general use for heads over 600 ft. with gate valves predominating, with a tendency in the last two years to use gate valves of the follower ring type for the highest heads. For heads less than 600 ft., butterfly valves seem to be gaining favor, for both the upper and lower positions in penstocks, although there are a number of instances where gate valves without follower rings have been used at the upper ends of penstocks at heads of 200 ft. or less.

Loss of Head in Valves

Reliable information on which to base comparisons of loss of head through the different types of penstock valves is very meager. In gate valves of the follower ring type, in which the follower ring is of the same diameter as the pipe and registers accurately with the pipe when the valve is open, the loss is unquestionably negligible. In gate valves without follower rings the cavities for the gate seat and guides must create considerable disturbance with consequent hydraulic losses, but there are no accurate data available on the amount of these losses.

In straightway plunger valves with carefully designed water passages the losses should be quite small.

In unbalanced needle valves with external control of the needle the losses are undoubtedly greater, due to the unavoidable bends in the valve body and to the disturbance caused by the needle stem projecting through the main water passage.

Messrs. Glenfield and Kennedy, Ltd., Engineers, Kilmarnock, Scotland, have published some tables giving estimated losses through large diameter-butterfly and plunger valves. They do not state how far these estimates are based on actual tests. Table I gives the published data as a matter of interest, and to invite comment on their probable degree of accuracy. The estimated losses in the 12 ft. x 9 ft. Johnson-Boving valve when plotted on log paper appear to lie on a line with a slope of 2, as shown in Fig. 1.

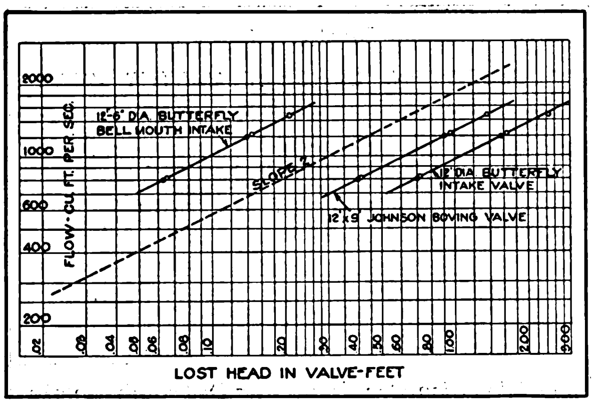

FIG. 1—LOSSES IN LARGE DIAMETER VALVES.

The following report on losses through butterfly valves has been furnished by E. A. Dow for the New England Power Company, and is the most comprehensive study of the subject that has come to the attention of the committee.

The data on head losses given in Table II are from tests in which pressures were observed at several points, as shown on the accompanying diagrams. An additional diagram (Fig. 2) is included showing friction head loss for 96 in. Dow valves which are located in the entrance to a pressure tunnel and, while not strictly penstock valves, they perform a similar duty, operating under a head of 110 ft.

A feature of interest in connection with the determination of head loss through butterfly or other valves is brought out in Fig. 3, which shows an apparent head loss at piezometer connection No. 4 greater than that at connection No. 5 farther downstream. The real loss may be still less than that obtained at point No. 5, but no connection below this point was available.

All tests made demonstrate that the entire loss through the butterfly valve occurs downstream from the center line where the jet is expanding, no observable loss having been found above the center line.

Use of Valves as Meters

The calibration of valves to serve as Venturi meters has been advocated. From the data available on loss of head, it would appear that the differentials given by head loss alone would be too small to give accurate differential readings. In many installations, however, particularly of valves close to the turbine, the reduction in diameter from upstream to downstream of the valve will give sufficient velocity differential in addition to the head loss to be measured accurately with instruments commercially available.

This is well illustrated by Fig. 5. The loss of head alone is very small, and being the difference between nearly equal magnitudes, the errors of observation are greatly magnified. The curve of total differential against flow, however, is quite smooth, and could undoubtedly be recorded accurately.

FIG. 5—LOSSES IN 60 IN. x 50 IN. BALANCED PLUNGER VALVE.

In predicting the power necessary to provide for operating valves of the butterfly type, the magnitude and relative time of occurrence of the maximum moment is often the most difficult to obtain. With a view to obtaining definite methods of attacking this problem, a series of tests were carried out, first on a 78-in. shaft-arm valve, then on an 8-in. model disk-arm valve, and the results were compared with similar data on an 8¼-in. manufacturer's standard shaft-arm valve. The two tests and the comparison are shown in Figs. 6, 7 and 8.

In the process of producing a workable method of computing these moments, an expression was adopted of the form

$$M = KD^3V^2$$

where D is the diameter in feet and V is the velocity through projected discharge area. By substituting the test values at various disk positions and solving for K, a series of values was obtained, which have been plotted as the curve of Moment Coefficient "K." The three sets of data show very similar shapes of the "K" curve, with the maximum

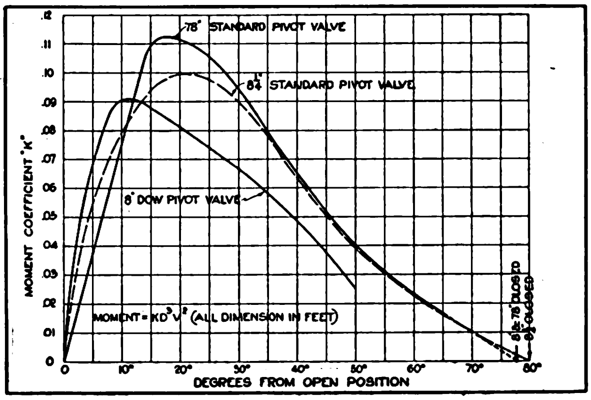

FIG. 6—COMPARISON OF MOMENT COEFFICIENTS FROM VARIOUS PIVOT VALVE TESTS.

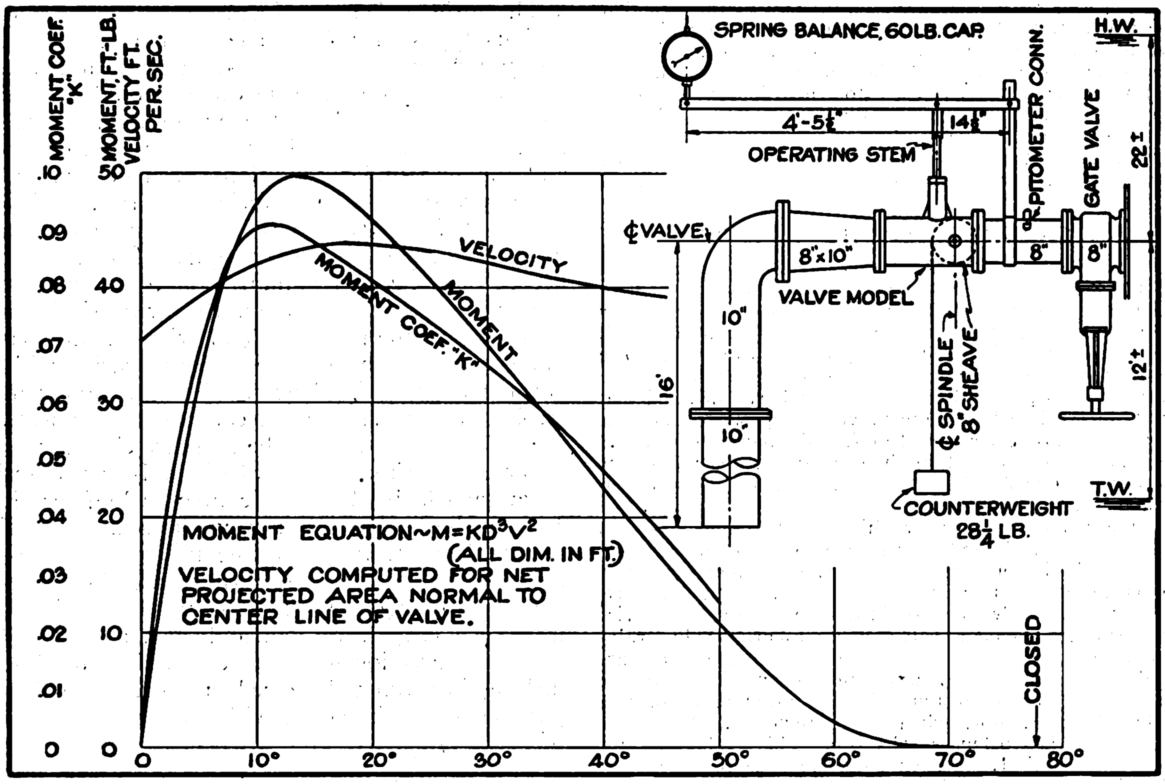

FIG. 7—Moment Characteristics of 8-In. Model Dow Pivot Valve.

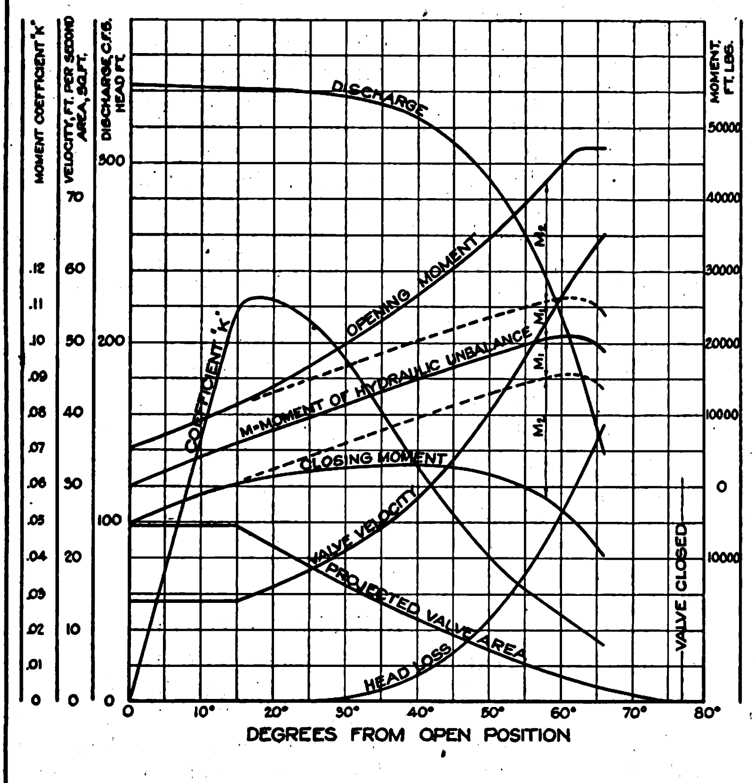

VALVE DATA ~ Diameter 78"

Disc thickness 16"

Spindle diam. 10"

POWER ~ 20" Hydraulic cylinder using penstock water at 250 ft. head.

TEST ~ Valve was oscillated thru a small angle each side of each nominal angular position. The operating force required while moving thru nominal position was determined from the pressure gages connected to each end of the operating cylinder. The discharge was indicated by the venturi meter. Areas were taken from design drawings.

TEST DATA ~ M = Moment due solely to unbalance of hydraulic forces, friction having been deducted.

M_1 = Constant moment due to friction inherent in the mechanical construction and independent of applied forces.

M_2 = Variable moment due to friction of applied forces.

EQUATION ~ $M = KD^3V^2$
(all dimensions in feet)

FIG. 8—Moment Characteristics of 78-In. Butterfly Valve.

at nearly the same angular position, in spite of the fact that in the actual tests the velocity variation differed widely in the 78-in. valve and 8-in. model, the former rising sharply with closing motion, the latter holding relatively steady.

In this formula "M" is the Moment (foot pounds) of hydraulic unbalance always tending to produce closure. It is the moment which would exist if all mechanical friction were eliminated. Friction acts to increase the opening moment and decrease or even reverse the closing moment.

Rugged Control Mechanism Essential

"The results of the tests demonstrate the necessity of a very rugged control mechanism for a valve used to control free discharge service such as a synchronous by-pass, or high head reservoir outlet. The most severe condition which would ordinarily be imposed on a penstock valve is closure with the turbine gates open. This is a comparatively easy condition to design for, but it should be borne in mind that a break in the line below the valve may produce moments approaching those encountered in free discharge service and the design of the control mechanism would depend on the importance and probability of having to close the valve in such an emergency.

All the valves covered by this report complete a full stroke under normal conditions in two to five minutes.

In general, the operating mechanism of these valves is such as to maintain rigid control of valves at all parts of stroke. The only one provided with a restoring device is the balanced plunger valve at Searsburg. This valve is controlled by a piston valve of which the ports are shifted toward neutral by mechanical connection with the plunger. The control piston valve is moved at a constant rate by electric motor, which is in turn controlled automatically by the turbine mechanism. This is because the station is an entirely automatic one and the plunger valve is closed during all shutdown periods.

Demonstration of ability to close with turbine gates open has been made in tests on the 78-in. valves at No. 5, the 96-in. valves at Davis Bridge and the balanced plunger valve at Searsburg. The design of the others, especially the disk-arm pivot type, is such as to permit safe closure even under free spouting velocity such as would result from a rupture below the valve. Closure of a penstock butterfly valve with turbine gates open, as in the case of a gate valve under similar conditions, results in a loud roar as the control passes from the turbine to the valve. The valve housing may be felt to tremble, but no shocks are experienced and no damage results if the control mechanism is of a suitably rugged design.

The Sherman valve and the 96-in. upper valve at Davis Bridge are equipped with remote control apparatus to permit emergency closing from the power house, but require an operator on hand to open them.

No by-passes are provided for the disk-arm valves, but the plunger valve at Searsburg and the lower butterfly valves at Davis Bridge are provided with relatively small by-passes. The plunger valve by-pass is not used, but the Davis Bridge butterflies are provided with snap rings, which produce so much friction that it is necessary to fill the scrolls through the by-passes before the main valves can be opened. This is a serious disadvantage at this plant, as it is necessary to keep the scroll cases drained to minimize motoring losses and the time required to fill the scrolls through the by-passes prevents the units from picking up load as rapidly as would be desirable in an emergency.

It is hoped that any engineers or manufacturers having knowledge of reliable tests on head losses and power required by various types of penstock valves will bring them to the attention of the committee in order that the results may be published and made available to the industry.

The power required to operate penstock valves is not a deciding factor affecting the choice of type The total power is comparatively small, and the few times per year that the valve is operated the kilowatt-hour power consumption is negligible.

The estimated actual force needed to operate the various types of valve varies widely, according to the judgment of different designers, and further tests, especially on butterfly valves, would be of great value. For gate valves, the maximum force is that required to overcome the friction between the disk and the seat under conditions of maximum unbalanced pressure. The coefficient of friction is estimated at from 0.35 to 0.7, the more conservative designers using the larger figure. For unbalanced needle valves, the maximum force to be overcome is the hydrostatic pressure on the area of the valve opening plus the packing gland friction. In balanced plunger valves the operating force varies with the varying degree of balance at different points in the stroke; it is usually taken care of automatically by the leakage to and from the pressure chambers.

Some experiments on a 3⅞-in. valve are described in an article by C. B. McAulay, Chief Engineer, Joshua Hendy Iron Works, in the *Journal of Electricity,* Nov. 1, 1926. While the scale of this experiment is too small to permit extending the conclusions to large valves, the results show that there is a very large variation, and even a complete reversal of direction in the force required to close the disk against full unbalanced pressures. Further experiments of this nature with large valves would be of great value.

Space Required for Valves

The space required may be a factor in the selection of the type of valve, especially where the valves are to be located inside the power house close to the hydraulic units.

Gate valves with hydraulic cylinder operation or with outside screw and yoke and mechanically operated require a great deal of head room, amounting to at least four times the nominal diameter of the valve measured from the center line of the pipe.

Butterfly valves may be installed in a much smaller space than gate valves.

Needle and plunger valves have a maximum diameter of, roughly, twice their nominal size, and are four or five times as long as the same size gate or butterfly valves.

Relative Cost of Different Types

The cost of penstock valves varies greatly with the head, size and conditions of installation. In general, it may be said that within their respective limitations the relative costs of the different types, from the least to the most, are in the order of butterfly, gate valve, externally operated needle valve and straightway plunger or Johnson valve.

Reliability in Operation

Reliability in operation is of the utmost importance. In case of an accident to the hydraulic power unit or a break in the pipe line, the prompt closing of one of the penstock valves may be the only means of preventing loss of life and serious damage to the plant. For this reason valves of rugged design with a simple and direct control are preferable to valves with complicated automatic control which might not function properly in an emergency.

Gate valves have repeatedly been closed under full penstock flow and in a few cases under flows considerably in excess of the normal. Gate valves chatter and are very noisy in operation under these conditions, but no damage to the valves or pipe line has been detected due to such operation. In one case the cast iron leaf of a 42-in. gate valve under about 200 ft. head was completely broken due to vibration when closing under flow. This was replaced with a cast steel leaf which has since operated satisfactorily. An exactly similar valve under 200 ft. head operated satisfactorily when closed under the flow due to a ruptured penstock.

Butterfly valves have been subjected to spouting velocity while closing under emergency conditions without any apparent harm. The instances reported have been of valves at the upper end of penstocks under moderate head.

Externally controlled unbalanced needle valves have been used for many years under very severe conditions and are generally considered thoroughly reliable. The operating mechanism of such valves must, of course, be strong enough to stand full unbalanced pressure.

Balanced and partially balanced plunger valves operating under heads of 800 ft. or more have not proved as reliable under all conditions of operations as other types. However, for low and medium head installations they have proved satisfactory. In large balanced valves under high heads the balancing forces are enormous, often in the millions of pounds, and the pressure in the balance chambers is often maintained through a small clearance space around the plunger, or by a very slight cracking of the control valves. Variations in the hydraulic balance which are very slight relative to the forces involved bring very large forces to bear upon the plunger with a consequent tendency to irregular, jerky travel. In closing such valves under unbalanced conditions, there is a wide variation in the forces acting on the plunger during the stroke and a tendency for the plunger to accelerate in the last few inches of travel to its seat. In one instance, where a 60-in. balanced plunger valve was closed under a flow of about 300 second ft., the rapid closure in the last few inches caused a pressure rise of 80 per cent in the pipe line.

Tests have recently been made by the Western States Gas & Electric Company on 28-in. diameter gate valves and plunger valves under practically the same conditions of head and flow. The maximum static pressure above the valves was 820 lb. per sq. in. The maximum flow for the plunger valve tests was 90 second ft., and for the gate valve tests 114 second ft. In the tests on plunger valves the penstock was unwatered and the tests started with fairly low pressures, gradually increasing the pressure on successive tests until full static head was reached. The discharge of water was controlled by the pressure regulator at the turbine. In the tests on gate valves the penstock was not unwatered but the valves were tested for varying discharges with varying rates of closure, the pressure regulator again being used to control flow. The pressures during operation were recorded at various points in the penstock, as well as the time of closure.

Marked surges were set up in the penstock in the plunger valve tests, but not in the gate valve tests.

The following paragraphs are quoted from the company's report:

> These tests of plunger valves seemed to point out certain things that may be of interest:
>
> 1. That it is hard to balance a plunger-type valve under the varying conditions of action and reaction incident to the approach to final closure with water velocities such as are obtained in high head practice.
> 2. That the operating cylinder must have a wide margin of power and be provided with throttling ports independent of the control mechanism.
> 3. That the control mechanism must be very sensitive to any motion of the plunger, especially as the plunger approaches final closure.
> 4. That port valves in the control mechanism must be designed to be tight as regards leakage, and prevent wire drawing of water across final seats or ports.
> 5. That ample provision should be made for flushing silt out of all internal working parts.
> 6. That all flow passages should be made as nearly streamline and smooth as possible.
>
> In the tests on closing gate valves under discharge conditions there is a pronounced "chatter point." This seems to occur where the control of discharge shifts from the pressure regulator to the gate valve, although the "screaming" persists in continually lessening amount until final closure is made. This "chatter" is telegraphed through the water column to all gages. This phenomenon might be explained in this way. That, while the discharge orifice in the gate valve is being reduced at a uniform rate, yet this orifice is a very poor one from a hydraulic point of view. Water under high velocity past sharp edges with abrupt changes in areas and directions of flow undoubtedly set up swirling vacuum pockets and hydraulic impacts that might easily set up a mechanical vibration below the valve that would be carried by the penstock and water column, much as sound would be carried. While some pressure waves were undoubtedly set up, the charts taken did not have the characteristics of the plunger valve charts where true pressure waves were set up upon closure.

Leakage

Tightness is somewhat more important in valves at the lower ends of penstocks than at the upper end.

Gate valves and needle and plunger valves, properly designed, are absolutely tight, under the highest heads and in the largest sizes.

Butterfly valves are not absolutely tight, but if well designed the leakage is small, and the other advantages of this type for a particular location may offset the objection to slight leakage. Adjustable seat rings are used on butterfly valves by some manufacturers, and prevent much leakage around the rim of the disk. Most of the leakage occurs where the shaft enters the bearings.

The following report has been received from the Philadelphia Electric Company on the operation of the 27-ft. butterfly valves at Conowingo Station:

> These valves have been in service for approximately one year, and no trouble whatever has been experienced with the valve itself or the hydraulic operating mechanism. Some little difficulty was experienced initially with the rubber tube sealing device. This device consists of a rubber tube in which a spiral spring is inserted to hold the tube in the recess provided in the valve body during the closing operation. After the valve is fully closed, the tube is expanded by water pressure to form a seal between the

valve body and the casing. As a result of the early operations of the valve and sealing device, the spiral spring contracted lengthwise into the tube leaving several feet of the tube without support. This portion of the tube was thus allowed to come out of the recess and was crushed between the valve body and the casing during the closing operation. This trouble was remedied by fastening the ends of the spiral springs to the ends of the tubes.

One of these valves has been tested for leakage at the normal operating head. The leakage found was from .3 to .4 cu. ft. per second.

Table III gives the amount of leakage measured in tests of some butterfly valves.

TABLE III

LEAKAGE TESTS OF BUTTERFLY VALVES

Emergency Operation

Operation at spouting velocity is frequently given as a specification requirement. This is a severe requirement and is rarely met with in practice, although in the event of an accident to the power unit or a break in the pipe line, the ability of the valve to meet this condition is important, and it is for just such emergencies that penstock valves should be designed.

Specifications should state exactly what is meant by "Operation at Spouting Velocity." One interpretation is operation under conditions equivalent to the total removal of the conduit below the valve, resulting in the maximum discharge of which the upper conduit is capable, such as would result from a rupture in the part below the valve. The other interpretation is operation under conditions of the maximum normal flow through the conduit which results in the development of full spouting velocity as the valve approaches the closed position.

The first interpretation should be applied to valves in the upper parts of penstocks, where bursts may occur below them. For valves at the bottom of penstocks, the requirement might be made less, if the designer has sufficient confidence in the reliability of the hydraulic unit. One company has specified for a 96-in. butterfly valve under 700 ft. head that it must be capable of closing safely with a velocity of 100 ft. per second through the open valve. This is about half the full spouting velocity, and it is reasonable to assume that a break in the hydraulic turbine might never be so serious as to cause a greater discharge.

Operating Mechanism

Gate valves under high heads are usually operated by hydraulic cylinders taking their pressure from the penstock. The control of the pressures to the opening and closing sides of the piston may be by means of a small four-way valve, hand operated. Some recent designs, however, have used sleeve valves of various types, some without packing and some using cup leathers, operated by a small electric motor. Power for the motor is taken from a storage battery, to insure its operation in case of failure of the alternating current supply. Hand control is also provided. Hydraulic operation is particularly applicable to valves of automatic plants which may be arranged to close on failure of the control power.

Mechanical operation of gate valves under moderate heads, through screw stems and gearing, with electric motor drive and auxiliary hand control is very common practice. For high head gate valves of large size, the forces to control are so large that mechanical operating gear is not practicable.

The design of operating gear for gate valves, whether hydraulic or mechanical, should be carefully examined to see that it is adequate for the most severe conditions of operation. Trouble has occurred from stems buckling, threads cutting, due to excessive bearing pressure, and motors stalling, all as a consequence of under-estimating the power required to operate the valve under full unbalanced pressure.

Hydraulic or electric control is almost essential with valves of any considerable size, on account of the great length of time required to operate if hand power applied through mechanical gearing is used.

Gasoline engine drive has been used for very large valves as an auxiliary to electric drive, where the length of time required for hand operation would be too great. It is not suited to remote control, and is only desirable under special conditions. Electric operation, with two or more independent sources of power is considered the most compact, cheapest and simplest control for butterfly valves under most conditions.

Needle valves of the angle type are in use with both hydraulic and electric operating gear. The forces acting on the plungers of this type of valves are very large for high heads, larger than the force required to move gate valve disks, and it was the desire to reduce the power required to operate, and the cost of the heavy operating gear that led to the development of balanced plunger valves.

Balanced plunger valves have been used in a number of plants at the lower end of the penstock. Their operation depends on very critical balances of pressure, and while their operation under equalized pressure above and below is satisfactory enough, their operation under unbalanced pressure conditions or under full flow is considered hazardous, at least by the operators of fairly high head installations.

For lower heads, in Eastern practice, balanced plunger valves of the Johnson type are considered more favorably.

Attention is directed to an article published in the *Electrical World,* July 24, 1926, on the Wallenpaupack hydro-electrical development of the Pennsylvania Power & Light Company:

> The Johnson Hydraulic Valves used in this installation are Type "B" and Type "T" hydraulic control, operated by means of hand wheel, motor or solenoid valve. These Johnson valves can be operated either in the valve chamber from the switchboard or automatically, as is usually provided in a Johnson valve installation. The new feature of the design, however, is the provision for quickly opening the Johnson valves by means of the solenoid-operated valve in the piping of the Johnson valve.
>
> The operation of this solenoid valve will cause the Johnson valve to open about half way in four seconds. The valve will continue to open at this rate until nearly fully opened. At the end of four seconds, however, enough water will pass to carry approximately the full load of the unit. One-half second after the Johnson valve begins to open a contact will be made that will cause the turbine to be put on governor control and will start opening the turbine gates, bringing the unit up to no load speed. The unit can, therefore, be made ready for synchronizing with the line and loading up in a very short time.
>
> With this installation, the unit is equipped with a very long conduit leading up to a surge tank, and from there the water is led through a steel penstock to the Johnson valve located at the entrance to the turbine casing. The head on the plant is about 360 ft. In this case the putting of a unit on the line and building up load in a few seconds starting with the Johnson valve closed is a big step forward toward automatic operation.

The pressure for hydraulic operating cylinders is commonly taken from the penstock. Pressure from another source is sometimes provided in addition so that the valve may be operated for inspection or repair with the penstock empty.

In case of a break below the valve, the operating pressure available from the penstock is greatly reduced due to increased friction loss and conversion of pressure head to velocity head, and the operating cylinder must be large enough to close the valve with this reduced pressure.

The opening and closing time of penstock valves is specified anywhere from 2 to 7 min. One company has specified a 2-min. time for all butterfly valves regardless of size. For valves so located that pressure rise can be ignored, the rate is determined largely by mechanical considerations and varies from about 1 min. for the smaller valves to 3 min. for the larger ones. The permissible rate for valves at the lower end of long penstocks is governed largely by considerations of pressure rise and safety. The rate of movement of the valve plunger or disk should be uniform throughout the time of stroke, or should be slower during the last part of the closing stroke. In the earlier design of balanced plunger valves, there was a decided tendency for the valve plunger to accelerate during the last part of the closing stroke. When a valve is closed under normal flow, but with unbalanced conditions, as might occur when the penstock valve is used to shut off the flow to a turbine without closing the turbine gates, the flow through the valve does not decrease uniformly. When the valve is 80 per cent closed, the flow may still be more than 80 per cent of the initial flow, depending on the discharge conditions below the valves. Therefore, an acceleration of plunger travel during the last 20 per cent of the stroke may cause an excessive pressure rise in the pipe line. This condition has occurred in practice, and it was this defect in operation which led to the development of restoring mechanisms to control the rate of valve travel.

Restoring mechanisms have been constructed in various ways, but the object is to apply a retarding force or a reversal of force to the moving element of the valve in case it accelerates beyond a predetermined rate. For free discharge regulating valves, restoring mechanisms have been applied to hold the valve at some intermediate position, but this condition does not hold for penstock valves, and for them the sole object of the restoring mechanism is to limit and control the rate of travel.

Restoring mechanisms may be applied to the hydraulic operating of any type of valve, but are rarely used with gate or butterfly valves.

Needle and plunger valves, however, are subject to great changes in the hydraulic forces on the moving element during the transition from normal unrestricted flow to throttling, and since the mechanical friction is small in comparison the forces must be almost completely sustained by the operating cylinders or chambers. This means that there will be a tendency for the rate of movement of the plunger to change with the pressure differences. In case an exterior operating cylinder is used, as with the various forms of angle and offset needle valves, it is possible to use watertight pistons, in which case orifices in both inlet and exhaust pipes will give a stroke of sufficient uniformity for applications where pressure rise conditions are favorable. However, where absolute uniformity of stroke is required, a restoring mechanism on the control valve is essential. Needle valves where the pistons permit some leakage, and straightway plunger valves where there must be a certain amount of clearance around the parts of the plungers that form the working pistons, require restoring mechanisms.

Automatic emergency closing devices are not yet in use in any of the plants reported on. One company, however, is just completing the installation of such devices just below the upper valves on all of its more important penstocks. In this device an increase in velocity in the penstock of, say, 50 per cent above the normal maximum will cause an increase in the differential pressure at a slightly contracted section of the pipe. The increase in differential pressure will operate a relay which, in turn, will close the electric circuit of the valve motors.

Remote control for operating the upper penstock valves from the power house switchboard is generally standard practice. Some companies restrict their remote control to closing only, and make it necessary for an operator at the valve to control the opening. This practice eliminates a certain amount of hazard due to a possible accidental or mistaken opening of the valve when men are working below it. Remote control of both closing and opening is the usual practice.

Details of Design

The allowable unit stresses in valves parts depend on the importance of the installation and vary somewhat with the type of valve. In general they should be the same as for other high grade machinery of the same character. With the increase in sizes and pressures, marked economies have resulted from the use of high strength alloy steels and bronzes for certain vital parts and for bolts.

The details of valve seats vary widely with the type of valve and with different manufacturers. For seats with sliding contact, various types of bronzes have been used, with a tendency on the part of some to follow the recommendations of the U. S. Bureau of Reclamation for the composition of the bronze. Seats and disk rims of butterfly valves are usually specified to be bronze, but the composition of the bronze is usually left to the manufacturer's judgment. Needle and plunger valves have only pressure contact between seats and the materials used vary greatly. Such valves have been made with seats of steel, of bronze, of bronze on steel and steel on bronze. There is no definite opinion as to the best practice.

Seats of small heavy gate valves are usually peened in, and for the larger sizes clamped in place between adjacent parts or screwed in.

In some plunger valves the seats are circular and of roughly triangular cross section, pressed into the valve body or shrunk on the plunger. Some difficulties have been experienced due to these seats working loose, and in some cases coming entirely out. Bronze rings cannot be reliably attached by shrink or press fit alone, and the best practice for bronze seats is a positive bolted or clamped fastening.

The unit pressures between valve seats have been the subject of much discussion without any definite conclusion. For seats in pressure contact only, as in plunger valves, the pressures in some valves now in use are several thousand pounds per square inch, and no troubles have been reported due to these pressures. For gate valves some attempts have been made to limit the contact pressures, with the valve fully closed, to 500 lb. per sq. in. For small or low pressure valves this is possible, but on large gate valves for extremely high heads, the seat pressures cannot be reduced in some cases below 2500 lb. per sq. in., and it would appear more logical to develop bronzes or other alloys to withstand these high rubbing pressures than to attempt to enlarge the contact surfaces.

Furthermore, in gate valves, having annular seat and disk rings, the entire seat pressure is concentrated upon two small diamond-shaped bearing areas as soon as the disk has been raised a small distance. Bearing pressures in this case may amount to twenty times the pressure on the seats in full contact. To obviate this, some gate valves have been built with side guides which are in contact the full length of the stroke.

Cylinders and pistons for hydraulic valve operation present no unusual difficulties. Cylinders are usually bronze lined, with arrangements for preventing the bulging of the liner should pressure get behind it. Pistons have been packed with cup leathers, flax packing and bronze snap rings.

Limit switches are commonly used in all motor operated valve gears, whether mechanical or hydraulic. Where motors are of considerable size, operating the valve through reduction gears, they should also be provided with solenoid brakes to prevent overrun and fix more definitely the operating point of the limit switch. Solenoid brakes have been found particularly desirable on motor operated butterfly valves.

Slip friction clutches between the motor and the valve gear are not considered reliable. When new the coupling may be set to slip at the proper torque, but after some time the setting will vary and cannot be relied upon. In a number of instances these slip clutches have been replaced by positive couplings.

Provision usually is made so that penstock valves can be moved from the line without tearing out the adjoining pipe. This has been accomplished by split ring bolted joints, by placing expansion joints close to the valve, and by providing a riveted flange that can be cut loose and driven back on the pipe. Gate and butterfly valves usually are arranged so that the parts most likely to wear can be replaced without removing the valve bodies from the line.

Conclusion

In presenting this progress report, it is hoped and expected that those who are interested in the subject, whether as designers, manufacturers or operators, will send in their comments on the statements made, and contribute any additional information which would be of value to the industry.

Actual operating experiences and tests particularly are desired. Further accurate information is wanted on the loss of head through valves, on the sliding friction between valve seats, the proper materials for valve seats, and the actual power required to operate butterfly valves.

MANUFACTURERS' STATEMENTS

The Hydraulic Power Committee does not accept responsibility for any manufacturers' statements.

STATEMENT BY THE ALLIS-CHALMERS MANUFACTURING COMPANY

Butterfly Valves

The Allis-Chalmers Manufacturing Company has always advocated the use of butterfly valves for penstock and casing inlet valves for heads up to 600 ft. and over. The company has now built these valves in sizes up to 27 ft. in diameter. Its position has been that a correctly designed and built butterfly valve represents the simplest, least costly, and more reliable type of valve from a mechanical standpoint. A shape of wicket has also been determined upon which makes this type of valve very comparable in head loss to other more expensive and complicated designs. The success of building butterfly valves to eliminate leakage has been largely a question of rigidity in the valve body in order to resist deformation due to exterior strains imposed by the penstock. In addition, this company always has been confronted with the problem of eliminating leakage around the shaft. In view of the fact that it is not always possible to eliminate deformation, various types of sealing devices between the outer periphery of the wicket and the valve body have been resorted to, with varying success. The device which is in most common use consists of a sealing ring placed in the outer diameter of the wicket and expanded against the valve body by means of the penstock water pressure when the wicket is in closed position. Fig. 9 shows these rings inserted in the wicket.

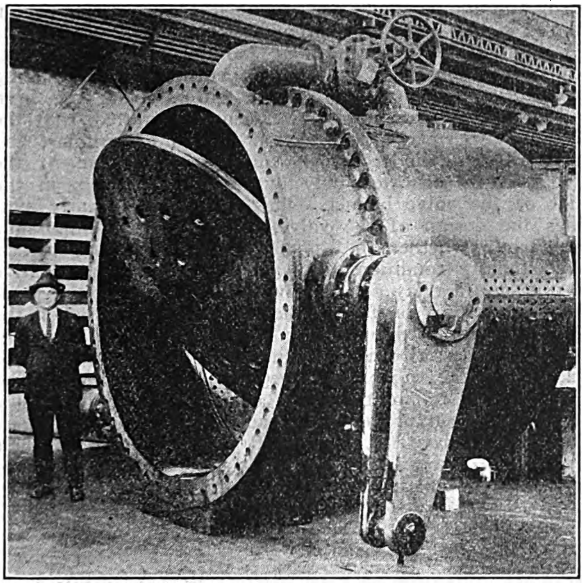

FIG. 9—96-IN. DIAMETER CAST STEEL BUTTERFLY VALVE.

For the Conowingo butterfly valves, a new method of sealing is used by employing rubber hose set into the valve housing and subjected to pressure, thereby pressing same against the periphery of the wicket. Shop tests have proved very satisfactory, and it is expected that the field results will also show the desired results.

Practically all butterfly valves of any size, and especially those built for the higher heads, are tested at the factory before shipment. The leakage of a 108-in. valve in such a test was less than 1 gallon per second under 200 lb. pressure. Table IV lists actual leakages as obtained under shop tests with various sized valves and under various pressures.

It has been common practice with this company to make the valve bodies and wickets of cast steel in all cases except where the stresses are unusually low due to small sized valves and low head. In the case of the Niagara Falls valves, the wickets were made of steel plate with cast steel end pieces and cast steel outer rings. The plate steel construction of wicket was found to be very acceptable for this operating condition. The Conowingo butterfly valves, which are 27 ft. in diameter, were made with wickets of cast steel on account of higher stresses due to a head of 90 ft. in the place of 60 ft. head with the Niagara Falls valves, and also due to the fact that the water contained a great many impurities that were conducive to corrosion.

TABLE IV.
BUTTERFLY VALVE - LEAKAGE TESTS

SIZE INCHES	TEST PRESS. LBS/SQ. INCH	WORKING PRESS. LBS/SQ. INCH	LEAK. UNDER TEST PRESS. G.P.M.	LEAK. UNDER WORKING PRESS. G.P.M.

84	175	90	27	12
108		185		28
84	225	150	33	27½
108	185	100	102	65
96	125			28
84	A VALVE			25
84	B VALVE			21
84	225	150	54½	49
84	175	100	52	26

The 23-ft. and 27-ft. diameter valves built for the Niagara Falls Power Company and the Susquehanna Power Company have vertical operating shafts, as it permits placing the operating mechanism directly over the casing or penstock inlets, and in this way does not necessitate any additional space on either side of the valve body. There is also an additional advantage in erection of this machinery, as with the operating shafts in the vertical position the sections can be split in a horizontal plane, which would not be practical in the case of a horizontal shaft, and the weight of shaft and wicket can be carried in a thrust bearing outside of the flow of water and accessibly lubricated. In the larger valves and under higher heads it is found necessary to provide a means of taking the water load on the wicket when it is in closed position and under full pressure.

Where it is desired to provide for removal of the valve, the company's standard practice is to make the face of one valve body flange at a small angle to the other face. In other words, the planes of the flanges are made wedge shape. Ordinarily with heads up to 400 ft. no packing is inserted between the penstock and casing flanges and the body flanges. With heads above 400 ft., provision is made for inserting a round rubber packing in a groove provided in the valve body flange. This groove is made tapered to the outside so that the pressure of the water will elongate the rubber ring, forcing it tight in the groove against the two flanges.

An important element that enters into the mechanical design of butterfly valves is the question of moment when closing the valve against maximum velocity. This moment varies in the ratio of the cube of the valve diameter and also the square of the velocity, and it has been found in many cases to represent a stress several times that encountered when opening or closing the valve under full penstock pressure but no velocity. This design feature together with a design of valve to resist deformation has usually resulted in a heavy design of valve compared with other standard designs which have been based largely on water works requirements.

Various kinds of operating devices have been used for butterfly valves. The common type is a motor and hand operated device connected to a lever mounted on one end of the operating valve shaft. In the larger valves it is necessary to go to a greater power ratio between operating mechanism and valve shaft, in which case a gear or worm segment is used. This type of mechanism has the advantage that normally it is under control of an electric motor with limit switches placed at the opening and closing position of the wicket to bring the valve wicket in correct position for opening or closing and to avoid overloading of the motor. In case of failure on the motor, the hand regulating device is used, and while considerably slower in operation, it provides a definite and positive means of closing or opening the valve. Operating mechanisms are all self-locking, so as to prevent motion of the handwheel due to reaction from the wicket. With the larger valves a mechanical operating device is cumbersome, and hydraulic operating cylinders have been substituted. With the higher heads, the operating pressure is obtained from the penstock with auxiliary means for operating the valve when no water pressure is available. In the case of the larger diameter valve and under low head, a separate oil pressure system may be used. This arrangement is satisfactory only if oil pressure is available under all conditions of operation. An operating cylinder was used for the Niagara Falls Power Company valve. The diameter of the operating cylinder is small on account of using an oil pressure system under 150 lb. working pressure, as compared with the stroke required for operating the valve. The control of the oil or water pressure to the operating cylinders can be made either hand or motor operated. A relay is sometimes placed on the control device so as to provide a uniform opening and closing rate of the valve wicket, or else diaphragms must be provided to limit the rate of motion.

Gate Valves

The Allis-Chalmers Manufacturing Company has not entered into the manufacture of gate valves to any appreciable extent except under high heads and when a special design of valve is required which is not included in the standard valve manufacturer's design. The company's principal contribution in this field has been in adding a follower ring onto the valve disk. This ring fills the opening required for the disk when in the open position, thus eliminating all eddy losses, protecting the valve seat against the scouring action of the flowing water, and preventing chattering of the valve disk because of a larger leverage guiding the sliding disk. The Allis-Chalmers high head gate valves have all been operated by means of cylinders which receive their operating pressure from the penstock. Fig. 10 shows the eight valves built in 1913 for the Big Creek plants No. 1 and No. 2 of the Southern California Edison Company. Here four hand-operated valves are used for the control and diaphragms are inserted in the piping leading to the operating cylinder, so as to limit the rate of travel of the piston, and the valve disk. A valve of similar but improved design has a single control valve of the sliding disk type instead of the four hand-operated valves. The control valve is hand, or motor-operated from the switchboard, and the contacts are provided for operating green and red lights showing position of valve.

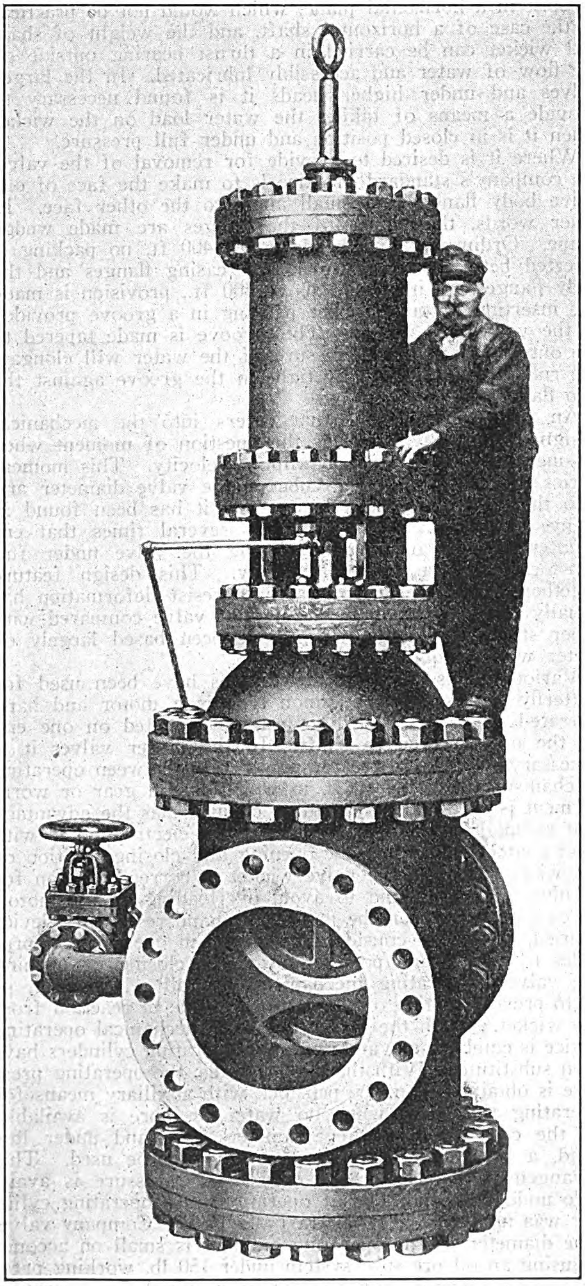

FIG. 10—24-IN. HYDRAULICALLY OPERATED GATE VALVE.

A 42-in. valve for a head of 350 ft. built by the company twenty years ago is still in operation without having required any repair. This valve differs from the high head design in that the follower ring is omitted, that the valve body is of elliptical section instead of circular, and the operating cylinder is not entirely independent of the valve, but is separated only by one packing box in the inside of the valve bonnet. This, of course, greatly simplifies the design of the valve, but renders it impossible to ascertain whether the submerged stem packing box is in satisfactory condition. This design makes it imperative to either use a relay for positive rate control, or the pressure must be left on top of the operating piston when the valve is kept closed under penstock pressure on upstream or on both sides, as otherwise due to leakage along the stem packing box the valve may creep into open position. The simplicity and reliability of the company's high head gate valves have been proved under actual operation for many years. They have not been used as extensively as their merit would warrant, but it is felt that greater consideration will be given this type of valve in the future.

STATEMENT BY THE COFFIN VALVE COMPANY

The only type of penstock valve furnished by The Coffin Valve Company is the Dow Disk-Arm Pivot Valve, and a description of this valve appeared in the 1924 report of the Hydraulic Power Committee. (N. E. L. A. Proceedings, 1924, pp. 802-803.) Since that time the company has furnished a considerable number of these valves, and so far as it has been able to check up on the actual operation of the valves, has found them to be eminently satisfactory.

The Coffin Valve Company has been able to make these valves remarkably tight and inclose a list of shop tests for leakage on various valves. It will be noted from this list that the tightness of the valves has gradually improved, due to improvement in design and workmanship. Where records were obtained from the field, it has been found that the leakage under actual working conditions has not exceeded that shown in the shop, and in some cases is much less. For instance, the 60-in. valve tested in the shop in March, 1926, showed a leakage of 1½ gallons. This was on account of the fact that the disk was not closed as tight as it should have been, and it was reported to the company by the customer that the valve, after it was put in the line, showed practically no leakage.

A successful automatic operation for these valves has been also worked out. Valves automatically operated have been generally installed in pump discharge lines, but where it is desirable that a penstock valve automatically close, this type of operation can be used. A sleeve type of control valve actuated by a solenoid is used by the company, and as long as the solenoid is energized the pivot valve will remain open, but as soon as the solenoid becomes de-energized, the pivot valve will close. Fig. 11 shows a valve of this type.

A method has been developed of operating valves by electricity which differs in principle from those now on the market. This company has always contended that the motor should not be shut off by a limit switch when a valve is closing, because the complete closure cannot be made by the motor and it is necessary to supplement this operation

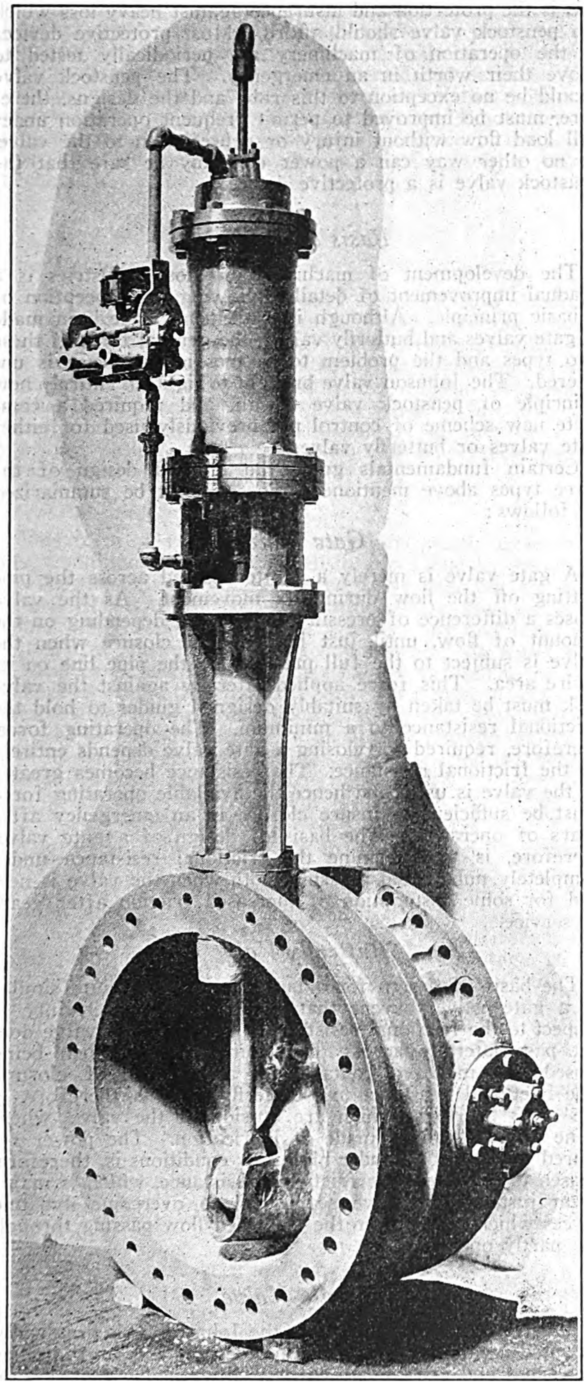

FIG. 11—PIVOT VALVE, HYDRAULICALLY OPERATED AND SOLENOID CONTROLLED.

by hand operation to obtain a tight valve. Use, therefore, is made of a multiple disk friction clutch, which contacts on the outside of the clutch, to take care of stopping the motor after the valve is closed. This type of operation is particularly adaptable to pivot valves because the tightness of the pivot valve depends on jamming the disk hard into its seat, and our type of motor operation completes this before the motor is stopped. Fig. 12 shows a 60-in. pivot valve equipped with motor operation. This valve is installed in a penstock just ahead of the turbine in the power plant of the Vermont Marble Company.

Mention should have been made above that the solenoid-operated sleeve type of control valve, used for automatic operation of hydraulically-operated valves, provides successful remote operation for hydraulically-operated valves.

STATEMENT BY THE NEWPORT NEWS SHIPBUILDING AND DRY DOCK COMPANY

Believing that the butterfly valve is the most economical type of penstock valve, with due consideration for features of reliability, long life and safety, the N. N. S. and D. D. Co. regularly build only this type. The constantly increasing demand for butterfly valves to be used under widely varying conditions of head and flow furnishes gratifying evidence of the correctness of this policy.

The Newport News valves are provided with a patented self-adjusting, renewable bronze sealing ring fitted to the valve disk, and special provisions are made to reduce the leakage around the shaft to a practicable minimum. Rubber composition sealing rings are not used because they are easily damaged and subject to excessive wear. Experience has shown also that a properly designed and manufactured adjustable metal sealing ring can be made amply tight for practically any service. As an example of this construction, a recently installed 150-in. butterfly valve showed a leakage of less than five gallons per minute under a head of 130 ft. Similarly, in case of a 102-in. valve under 52 ft.

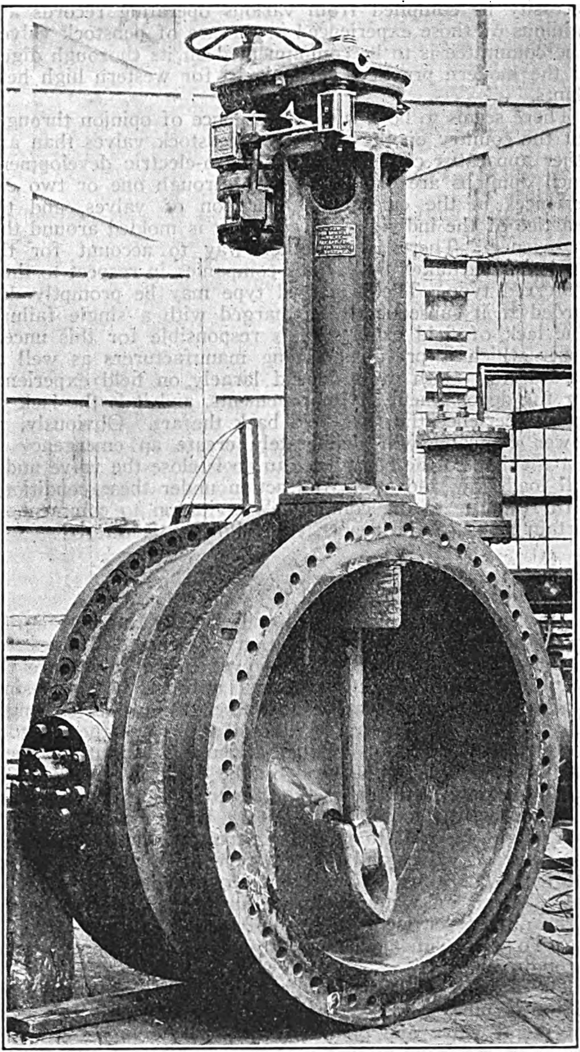

FIG. 12—60-IN. MOTOR-OPERATED PIVOT VALVE.

head, the leakage was reported as "too small to measure." Exceptional shop and crane facilities enable this company to handle advantageously valves of any practicable size and for any reasonable head.

A standard line of mechanical operating stands has been developed suitable for either motor or hand operation, or both. Where motor operated, a limit switch is provided to restrict the valve movement in either direction, and provision may be made for remote control when desired. Hydraulic operation will be furnished for any size valve if specified, but mechanical operation usually is recommended on account of the lower cost of upkeep, elimination of accessory equipment, such as pumps, etc., and the ease with which it can be made self-locking.

Little information is available relative to the power required to operate a butterfly valve under various conditions of flow. The company has investigated this in considerable theoretical detail, and steps are now being taken to supplement these data with a series of tests on an actual model valve in the Newport News Hydraulic Laboratory. It is expected that this series of tests will add much to the engineering information on this subject which is now available.

STATEMENT BY THE I. P. MORRIS CORPORATION

(Now I. P. Morris & De La Vergne, Inc.)

On account of the lack of test data the report must of necessity be compiled from various operating records and opinions of those experienced in the use of penstock valves. The committee is to be complimented on its thorough digest of the modern practice, particularly for western high head plants.

There seems to be a wider divergence of opinion throughout the country on the subject of penstock valves than any other apparatus connected with hydro-electric development. Such opinions are usually formed through one or two experiences in the emergency operation of valves, and the practice of the individual or company is molded around this experience. There is no other way to account for the definite stand taken by various companies in respect to their preferred type. The preferred type may be promptly discarded if it subsequently is charged with a single failure. The lack of field experience is responsible for this uncertainty which is prevalent among manufacturers as well as purchasers. Both must depend largely on field experience for the development of improvements, and it is the lack of such experience that has held back the art. Obviously, no power company will deliberately create an emergency to test a valve, so the best they can do is close the valve under full load flow and study the action under these conditions.

In response to the committee's invitation to comment on certain parts of the report, the following is offered:

Purpose and Location of Valves

This subject is well covered and there is complete agreement as to the suggested location of penstock valves for high head developments. The power house valves are the operator's chief protection against a break in the casing, broken guide vane links or any other failure which might cause a flood or runaway. Valves at the top of the penstock constitute a protection against a penstock failure. These latter valves, where the head on the plant is less than 250 ft., are seldom installed, as the danger of a broken penstock is exceedingly remote.

It might be well to consider carefully the real purpose for penstock valves and the service which they are intended to give. There are two operating requirements:

1. To shut off water from the turbine whenever a unit is taken out of service.
2. To close in an emergency with high flow passing through the unit.

The first is an operating necessity to permit unwatering of the turbine casing and inspection or repairs. A reasonably tight valve and one that will operate under balanced conditions will meet this requirement. The second is the requirement that should be adequately met by the design, as this is the protection and insurance against heavy loss which the penstock valve should afford. Most protective devices in the operation of machinery are periodically tested to prove their worth in an emergency. The penstock valve should be no exception to this rule, and the designs, therefore, must be improved to permit frequent operation under full load flow without injury or depreciation to the valve. In no other way can a power company be sure that the penstock valve is a protective device.

Basis of Design

The development of machinery in most industries is a gradual improvement of details following the conception of a basic principle. Although improvements have been made in gate valves and butterfly valves, the general form of these two types and the problem to be met in each case is unaltered. The Johnson valve brought to light an entirely new principle of penstock valve design, and required a complete new scheme of control not previously used for either gate valves or butterfly valves.

Certain fundamentals guide the finished design of the three types above mentioned. These might be summarized as follows:

Gate Valve

A gate valve is merely a shutter passed across the pipe cutting off the flow during its movement. As the valve closes a difference of pressure is built up, depending on the amount of flow, until just before final closure when the valve is subject to the full pressure of the pipe line on its entire area. This force applied laterally against the valve disk must be taken by suitably designed guides to hold the frictional resistance to a minimum. The operating force, therefore, required for closing a gate valve depends entirely on the frictional resistance. The resistance becomes greater as the valve is used, and hence the available operating force must be sufficient to insure closure in an emergency after years of operation. The basis of design of a gate valve, therefore, is to determine the frictional resistance under completely unbalanced pressure, both when the valve is new and for some assumption of increased friction after years of service.

Butterfly Valve

The basis of design for a butterfly valve is quite similar to a gate valve, except that there is less uncertainty in respect to the frictional resistance. The butterfly valve does not pass laterally across the seating surface when being closed, but makes a contact seat at the end of closure. The frictional resistance in a butterfly valve is, therefore, in the shaft bearings, which are outside of the valve, where some attempt can be made at lubrication. The power required for operation under high flow conditions is, therefore, chosen to overcome the frictional resistance, which is maximum just as the valve seats, and to overcome dynamic forces which result from the disturbed flow passing through the partly opened valve.

Needle Valve

A valve of this type, such as the Johnson or hydraulically operated needle valve, is a distinct departure from the other two types and involves an entirely different basis of design, since the friction element resisting closure is completely eliminated. The moving element of the Johnson valve travels parallel to the direction of flow, and hence cuts off the opening through the valve with the least possible disturbance. The motion of the valve element is exactly the same as a needle nozzle for an impulse wheel. The frictional resistance to closure being eliminated and the disturbed flow condition reduced to a minimum, makes this form of valve an easier design problem so far as determining the necessary operating force is concerned. The chief problem is to secure absolute control of movement irrespective of changes of pressure or flow. With this feature properly met by a simple and reliable control mechanism, the valve becomes the most reliable of any of the various forms.

The above discussion in respect to the basis of design of the three types shows that the gate valve must make use of either electric power or hydraulic power to overcome the frictional resistance when new and to make due allowance for increased friction after long periods of service. The butterfly valve has the same problem, except that with reasonable care the frictional resistance should not increase with service. There is no problem of friction in the needle type valve, but the problem here is one of a positive control mechanism.

Characteristics of Three Types of Valves

Gate Valve

This valve causes a moderately disturbed flow condition as it is closing, it develops high frictional resistance against closure, the bearing surface and seat deteriorate with service which decreases the reliability of the valve, and requires replacement of parts to prevent serious leakage. This valve is the least desirable of the three types to be used continually under high flow conditions. It is, therefore, not a proper design to test frequently for emergency service as suggested above.

Butterfly Valve

This form of valve could be tested frequently under high flow conditions, provided the disturbance due to the water passing through the partly opened valve does not set up a serious vibration. If such a vibration occurs, then the valve would better be operated in dead water only and could not be tested frequently for emergency service. Various forms of snap rings and spherical seats have been used to prevent leakage through this form of valve, but these devices are questionable, as the force holding the valve closed against the seat is not adequate. It is usual for butterfly valves to develop rather serious leakage after a period of service unless the seats are repaired.

Needle Valve

The needle valve is probably the most expensive form of valve, but it has two distinct advantages in that it can be operated safely and positively under any conditions of flow without appreciable wear or deterioration. It is the only type that can be safely tested at regular intervals for closure under high flow conditions. A further advantage is the fact that the valve seats on a diagonal surface with the full pressure of the pipe line against the moving element. This form of valve is therefore the tightest design and will remain tight with little or no repairs. Of the two types of needle valves the Johnson valve is the simplest form to install, as it does not require a bend in the penstock, but is self-contained with operating chambers incorporated as a part of the moving element.

Improvements Offered by the I. P. Morris Corporation

Gate Valve

Gate valves have been made by this company in the past, but they have proved very expensive if they are designed with sufficiently wide surfaces to insure frequent operation under unbalanced pressure. This form of valve has not been advocated by this company, as it is little, if any, better than the butterfly valve and is not as reliable as the Johnson valve. For this reason no improvements have been offered.

Butterfly Valve

Several types of butterfly valves are offered for penstock service, either operated hydraulically or by electric power. For high head valves a restoring mechanism is advocated if hydraulic power is chosen with the usual form of hydraulic piston cylinder element. In this way the motion of the valve element is held to a uniform rate and the proper operation is not dependent on the skill of an operator. The changes of force necessary to move the valve element are very pronounced under high flow conditions, and hence any fixed port openings in an operating cylinder would give a variable rate of stroke. A restoring mechanism, on the other hand, coordinates either a hand wheel or small motor with the movement of the valve element, and hence controls its rate irrespective of changes in the pipe line. The restoring mechanism is not required for low head butterfly valves.

The most marked improvement in this field is the rubber seal ring, which has recently been adopted for the 27-ft. Conowingo butterfly valves. A rubber tube is inserted in a recess located in the valve body. When the valve disk is moved to its closed position the rubber tube is expanded by water pressure so that the surface of the tube bears hard against the periphery of the disk. This cuts off leakage entirely through the valve and renders a butterfly valve exceedingly tight. The flexible nature of the rubber has another advantage in that it will conform to the edge of the disk, even if it be slightly off center or if it be damaged by closure against an obstruction. The rubber will follow any slight depressions or close around sticks or other foreign matter which may adhere to the edge of the disk. This characteristic makes the rubber seal preferable to any form of mechanical seal such as snap rings or spherical seats. Shop tests have indicated the entire success of this form of seal and indefinite life for the rubber is assured by the rubber companies since it is located in water and kept away from light.

In large valves, such as the 27-ft. diameter Conowingo valves, the rubber tube is 3-in. outside diameter and 2-in. inside diameter. The valve disk is somewhat smaller than the inside bore of the body, so that when closed there is a 3/16-in wide opening around the disk. This opening is closed off completely by expanding the rubber tube. When the valve is to be opened the pressure in the rubber tube is exhausted, allowing it to assume its original circular form and opening the 3/16-in. wide space around the valve. The operating gear of the valve and the pressure supply and exhaust for the rubber tube are interlocked so that the rubber tube can be supplied with pressure only when the valve disk is closed. Smaller sizes of valves would require smaller tubes and less clearance space around the disk. Incidentally, the clearance space around the disk can be used to good advantage for priming the wheel casing prior to operating the valve.

Tests of the Conowingo valves showed a leakage of 0.28 sec. ft. at 89 ft. head, and a deflection of the center of the valve disk of 0.14 in. under the normal head of 89 ft. and 0.27 in. under 127 ft. test head.

Johnson Valve

The original design and form of Johnson valve has remained unaltered since the first installation in 1910. The development in respect to this valve has been confined almost exclusively to the control mechanism. Even this has not offered a serious problem until high head installations were encountered, where dynamic forces and the pressure changes during the closure of the valve occur suddenly. For low head valves an ordinary four-way cock or ported piston valve are amply sufficient to control the movement of the plunger even when used by an inexperienced operator. This basis of control has been altered and extended to include a means of automatically priming the casing and effecting automatic closure of the valve in case of a break in the wheel casing. During the past three years the ported piston valve has been used almost universally in conjunction with a restoring mechanism so that the movement of the valve plunger is controlled with precision and pre-determined by the speed of a hand wheel or electric motor.

In closing the valve with this form of control and in flowing water the valve plunger cuts off the opening through the valve for the first part of the stroke but with little or no change in the amount of flow until spouting velocity exists. From this point on the plunger completes the closing stroke and cuts off the flow. There is no problem involved in controlling the plunger during the initial part of the closure stroke or during the final part of the closure stroke. The first part of the stroke is made with no appreciable pressure difference on the two sides of the valve plunger. Therefore, the control mechanism supplying and exhausting pressure to the operating chambers is leading the movement of the plunger. At some intermediate point in the stroke the pressure difference will become great enough to cause the plunger to lead the control and reverse the setting of the control valve. From this point on the plunger will continue to lead the control until it is closed. The movement of the plunger during the transition from a following to a leading position must be coordinated with the restoring mechanism and lap on the control valve so that only a slight motion of the plunger is necessary to reverse the setting of the control. For low head valves this has been very easily met by merely choosing a proper percentage of restoring and a proper lap and width of ports in the control valve.

In view of experience in high head developments, it seemed advisable to develop a control which would make use of a restoring mechanism without levers or gears of any description. In this way the lost motion present in most control mechanisms is entirely eliminated and the restoring effect is secured directly between the valve plunger and the control valve itself. The valve is a combination of the original penstock valve and the present well-known free-discharge regulator used for continual service in controlling the flow in dam outlets. Very desirable operating characteristics are secured in this manner as the control valve is operated at an entirely definite and pre-determined rate by the outside mechanism, while the plunger must follow exactly the motion of the control due to the exact coordination between the control valve and the port in the nose of the plunger. Whenever a point in the stroke is reached where the plunger tends to lead the control it requires only about ¼-in. motion of the plunger to produce the proper corrective effect on the opening through the port in the nose of the plunger. This transition takes place when the pressure in the flow line beyond the valve drops to 8 or 10 lb. per sq. in. below the pressure in the valve body regardless of the amount of flow. Therefore, there is no change in the rate of stroke of the plunger when the larger pressure changes occur just as the flow is approaching spouting velocity. The seat ring inserted in the neck of the valve body is recessed to permit some travel of the plunger after the flow has been entirely cut off. When the valve is closed with a very slight flow the pressure change occurs close to the seat. The recess is used to provide for uniform motion of the plunger under extremely small flow conditions when the pressure change occurs close to the seat. The conversion to the characteristic form of free discharge regulator is made long before free discharge takes place and hence the motion of the plunger is precise during the entire range of high velocity conditions.

Loss of Head in Penstock Valves

The information available in this company's records in respect to this subject is confined to loss of head through Johnson valves. Various reports have been received from different sources showing the loss of head through butterfly valves and the figures seem to indicate that there is little to choose between a butterfly valve and a Johnson valve so far as this feature is concerned.

The Johnson valves manufactured by this company are carefully formed to minimize the loss of head and a large accumulation of test data from various installations has fairly well established the loss of head curve shown on Fig. 13. The test data have been compiled from valves ranging in size from 4-in. outlet diameter to 14-ft. outlet diameter. The actual field figures have varied from 2/10-ft. to 8/10-ft. for the medium size valves, but the inconsistencies can generally be accounted for.

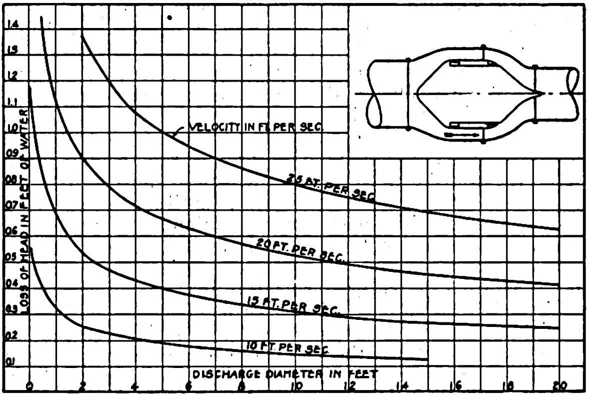

FIG. 13—LOSS OF HEAD IN JOHNSON VALVES.

It is a well established fact that piezometer measurements taken close to the valve outlet show losses higher than exist. Several piezometers located at short intervals beyond the valve outlet show increased readings for a distance below the valve equal to about two diameters. Whenever readings are taken for establishing loss through a valve of this form, it is important that they be taken at a point about two diameters below the valve and then corrected to allow for the friction in this length of pipe.

A long series of tests were conducted at the Queenston Station of the Hydro-Electric Power Commission, Niagara Falls, Ontario, and at Shawinigan Falls, Quebec, to establish correct figures for loss through a Johnson valve. These tests, together with miscellaneous tests on smaller valves, have affirmed the accuracy of the accompanying curve.

Conclusion

This company believes that the improvement in respect to making tight a butterfly valve is a distinct advance in the art and offers a reliable and positive sealing device. The revised control of the Johnson valve has definitely answered any uncertainties in respect to the movement of the plunger when pressure changes occur in the pipe line and renders this form of valve just as reliable in every respect for high head plants as it has proved for years past in low and medium head plants. A valve chosen and purchased for entirely safe operation under all conditions of flow should be tested frequently to prove its complete reliability. The Johnson type of valve therefore is offered by this company as the best suited to meet this specification.

Many power companies have never had occasion to depend on a penstock valve for closure under high flow conditions and therefore do not attach great importance to the emergency or insurance value of such a valve. For this reason their requirements are confined to stop valve service and they are prepared to run whatever risk may exist in the closure of their penstock valve in an emergency. The butterfly valve with the rubber sealing device is manufactured by this company to meet these less severe operating requirements.

Johnson High Pressure Penstock Valve

Fig. 14 shows the form of valve described. The plunger or moving element, A, is in the wide open position, allowing

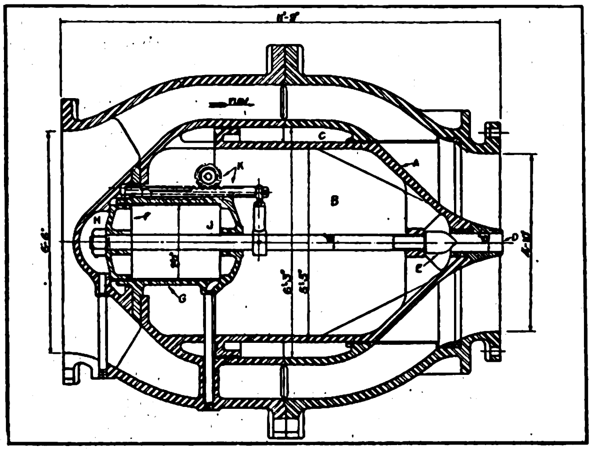

FIG. 14—JOHNSON HIGH-PRESSURE PENSTOCK VALVE.

water to flow in the direction of the arrows. The two main operating chambers, B and C, supply the necessary force for moving the valve plunger. An orifice, D, is closed or opened by a pilot valve, E. The pilot valve in turn is operated by piston F, contained in the cylinder G. The supply of pressure to chambers H and J of the operating cylinder, is controlled through a four-way needle valve located on the outside of the main valve body. Communicating pipes are shown leading into chambers H and J. The motion of the internal pilot valve E, is transmitted through a rack and pinion, K, to the exterior of the valve. The pinion shaft passing through the valve body is arranged with a restoring arm coordinated with the four-way needle valve so that piston F can be moved in the cylinder at a regular and predetermined rate. If desirable, in some installations, the rate of movement of piston F can be automatically retarded when the main valve plunger is approaching the seat.

To close the main valve, pressure is exhausted from chamber J and supplied to chamber H. Operating chamber C is connected at all times with the main water passage, while operating chamber B also has a restricted communication with the main water passage. The first motion of piston F causes pilot valve E to close off orifice D. The plunger is moved toward the seat by the force developed in cylinder G, so long as there is little or no drop in pressure beyond the valve. When a slight drop of pressure occurs, plunger A will tend to lead pilot valve E, thus opening the orifice D and establishing communication through the orifice with chamber B. The plunger is now moving forward by hydraulic pressure in chamber B, which is sufficiently higher than the pressure beyond the valve to overcome the slight friction and the pressure in chamber C. This is the characteristic regulating valve control wherein the pressure in chamber B is automatically controlled to hold the plunger in exact balance throughout the stroke. Any tendency for the plunger to move away from the control valve E, would open wider the orifice D and thus lower the pressure in chamber B so that no further forward movement is possible. The plunger will follow exactly the movement of the pilot valve and hold automatically a fixed relationship to maintain a perfect hydraulic balance of the plunger throughout the stroke.

When the valve is finally closed, the main plunger seats in the neck of the valve body and the pilot valve E shuts off completely the orifice D. To open the valve, the pilot valve E is opened first to discharge pressure from chamber B. As soon as the orifice is opened sufficiently to drop the pressure in chamber B to about 25 per cent of normal pressure, the valve plunger will be unseated and the casing primed through the main valve. The balance of the opening stroke is performed hydraulically if there is considerable flow through the valve. If there is little or no flow through the valve, the final opening is produced by the force established in operating cylinder G.

The valve can be arranged to close automatically in case of a break in the wheel casing, the closure taking place at the same rate as when operated for regular service.

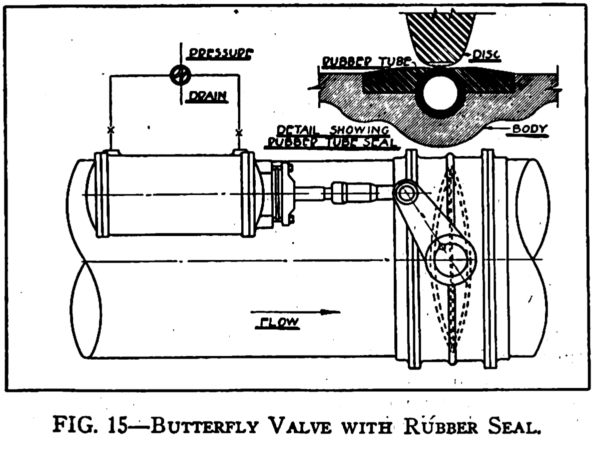

FIG. 15—BUTTERFLY VALVE WITH RUBBER SEAL.

Butterfly Valve with Rubber Seal

Fig. 15 shows the general outline of a hydraulically operated butterfly valve and an enlarged detail illustrating the manner in which the rubber seal is expanded against the edge of the valve disk. The rubber is held in position by suitable strips which are removable in case it should ever be necessary to replace the rubber.

MEMORANDUM REGARDING EMERGENCY CLOSURE OF JOHNSON VALVE FOR NO. 15 UNIT AT ONTARIO POWER CO., NIAGARA FALLS, ONTARIO

Written by G. O. Phelps, Supt.

The valve is a 9-ft. diameter type B Johnson valve operating under a static head of 60 ft. and designed to withstand a total head of 90 ft. This valve is used to cut off the supply of water to No. 15 unit at the Ontario Power Company, Niagara Falls, Ont.

The valve was installed and placed in commercial service June 19, 1919, and was used on an average of once in two weeks for shutting down the unit.

On April 20, 1922, an accident happened to the unit, resulting in a broken wheel casing, and the valve was used to cut off the flow of water which was pouring on to the

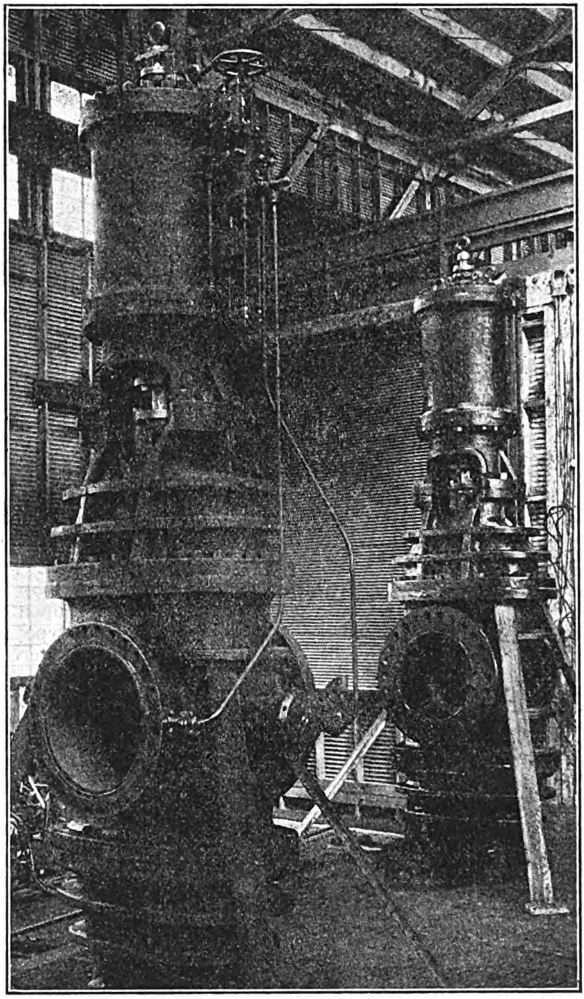

FIG. 16—28-IN. PELTON HYDRAULICALLY OPERATED FOLLOWER RING GATE VALVES.

main power house floor. An interval of approximately four minutes elapsed from the time that the casing was broken until the valve was shut, three minutes of this time being necessary to telephone operator and allow him to reach the valve.

The valve was closed without any trouble at all, its closing characteristic in this emergency being the same as for ordinary operation. The water was discharging through the outlet of the valve at approximately spouting velocity.

The value of this service in an emergency might be best illustrated by stating that if it were not for the quick and safe operation of the valve there would have been ten additional 11,000 h.p. generators flooded and rendered unfit for service for a period from three to four months. The loss of this power over such an extended period, involving not only loss in revenue and the cost of putting the machines back into service, but also the resulting loss to manufacturers and customers who would be forced to close down during this period is an item, the amount of which would total up into the millions.

The valve was left in the closed position and was not touched for a year and a half, during which time the unit was rebuilt and this end of the power house restored to its original condition. On Dec. 1, 1923, the unit was completed and the Johnson valve opened to prime the penstock and supply water to the turbine. It is interesting to observe that the valve opened in exactly the same manner as though it had been in regular operating service, in spite of the fact that the manufacturers advise the operation of this type of valve at least once a month. The sliding surfaces consist of brass plate against cast iron and in spite of its long period of idleness, there was not enough corrosion on the cast iron to have the slightest effect on the opening of the valve. It might also be added that during the year and a half of rebuilding the unit the penstock below the valve was perfectly dry, there being no leakage whatsoever around the valve seat.

The valve is normally opened in about one to two minutes and closed in about one minute, and the priming of the penstock is accomplished by just cracking open the valve and allowing it to remain in this position until the penstock is completely full of water. This particular valve and others like it in this plant are not equipped with the automatic closing device which is being used on the valves manufactured today. Had this been in use at the time these valves were purchased it is believed that the valve would have closed instantly following the break and the flood in the power house would have lasted for a space of about one minute rather than four minutes.

STATEMENT BY THE PELTON WATER WHEEL COMPANY*

High Head Penstock Valves

In the fall of 1928 this company completed shop test and successfully finished an exhaustive field test upon two 28-in. hydraulic cylinder operated follower-ring type gate valves with automatic hydraulic controls. These were installed at the El Dorado Plant of the Western States Gas & Electric Company on the American River, California, and operate under a head of 2111 ft., for which a test of 1575 lb. per sq. in. was required. They were operated under conditions approximating as closely as possible, emergency closure under unbalanced conditions, and were found to perform with entire satisfaction.

In addition to these two gate valves, four 32-in. hydraulic cylinder-operated gate valves have just been put into service for controlling main power water supply to two of this company's double overhung water-wheel units, carrying loads in excess of 45,000 h.p. each under a head of 2230 ft. These are for the Serra Plant of the Sao Paulo Tramway, Light & Power Company not far from Santos in Brazil.

A recently completed contract for the Feather River Power Company includes five 26-in. hydraulic cylinder-operated gates with automatic hydraulic control of our patented type. Four of these valves are for main power house control to two 30,000 h.p. double overhung Pelton water-wheel units, and the fifth is for shut-off purposes in a cross-connected pipe upstream of the water wheel gates.

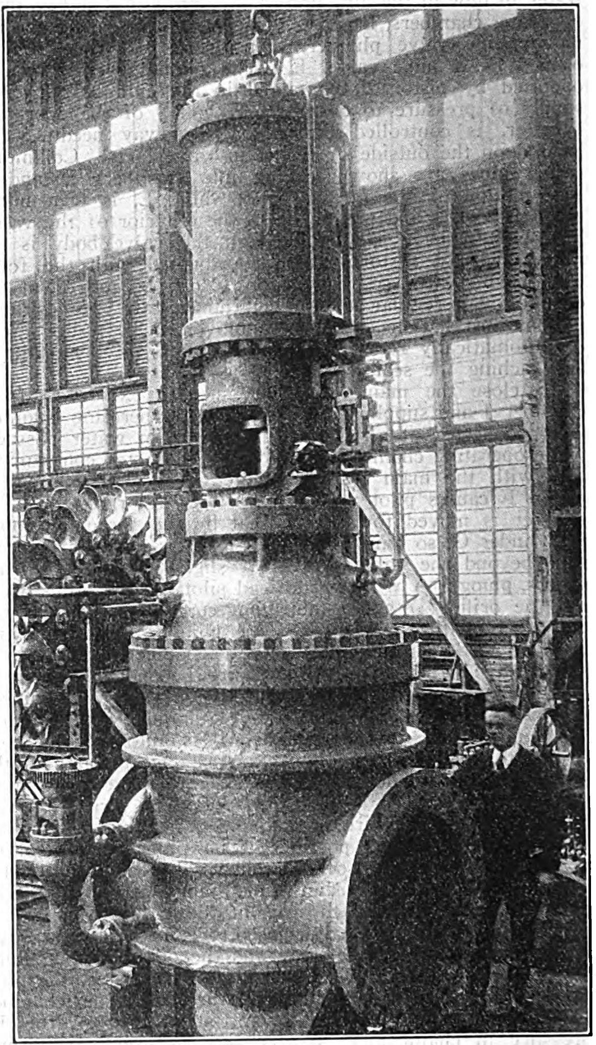

FIG. 17—32-IN. HYDRAULICALLY OPERATED GATE VALVE.

In addition, a Pelton water-motor-operated gate valve is being constructed for operation under 1400-ft. head. This is the fifth gate valve of this kind in use at the Drum Power House of the Pacific Gas & Electric Company.

Butterfly Valves

Recent installations of butterfly valves for penstock purposes include three 108-in. for main power water control to three 33,000 h.p. Pelton turbines at the Pit No. 3 plant of the Pacific Gas & Electric Company. The highest known head to which a butterfly valve has been used as a main stop penstock control, it is believed, is the one at the Oak Grove Plant of the Portland Electric Power Company. This valve operates under 930 ft. head and controls water supply to a 35,000 h.p. vertical turbine. Butterfly penstock valves are under construction in our shops at the present time for heads as high as 700 ft.

Most of these valves are electric motor operated, although one recently completed and installed for the Glines Canyon Plant of the Northwest Light & Power Company is hy-

draulic cylinder operated and is fitted with several automatic features which provide for its control by full automatic method in connection with the main unit which is itself of 17,500 h.p. capacity and the largest single automatic station yet attempted.

General

The developments and design of penstock valves for all heads whether high or low and whether of gate valve, Johnson needle valve, or butterfly valve types, have been perfected extensively in the past few years. All have been successfully put into service under the most trying conditions and their controls have been made extremely safe. All of the designs are adaptable to automatic plant operation.

A selection of a proper valve for any service requires a complete understanding of all of the conditions that are peculiar to each individual installation. It is the opinion of this company that no conclusion as to the proper penstock valve for any service should be reached without individual study.

SPILLWAY GATES ON OR ADJACENT TO DAMS

INTRODUCTION

An abundance of excellent material in the form of articles and papers published on the subject of spillway gates, or directly contributed by members of the Committee, was available for this report. The problem has been that of selection and reduction, with the idea always foremost in mind to produce a report that would include typical examples of the several types of gates under consideration, and at the same time reflect the best engineering practice in the different parts of the United States and Canada. Considerable valuable information also was gathered from European sources. It is realized that the report does not begin to cover the field of spillway gates, either from the standpoint of examples, or with respect to all the details that enter into the design and construction of a single type of gate. Time and available means for publication both precluded an attempt at too complete a treatise on the subject. Not the least among the useful features of the report is the bibliography found at the end. The scope of the subject is at once apparent when one considers that the extensive bibliography includes only matter published during the past five or six years.

It should be pointed out here that the report is confined to the design, construction and operation of spillway gates in actual use by operating companies. An endeavor has been made to select typical installations and types of equipment which might be of interest and value to operators and designers of such gates. Some data have been taken from the 1924 report of the Hydraulic Power Committee of the N. E. L. A. without specific reference.

There is an increased tendency to install permanent and substantial crest gates on dams rather than renewable flashboards. Clear-crest dams have become the exception rather than the rule. There still remains considerable room for improvement in the design of deep-crest gates and their operating mechanism to insure simple and reliable operation and low maintenance, as well as low first cost. Recent floods in several sections of the country, particularly in California, with intensities of runoff in many cases more than twice as great as any previously recorded, have shown the necessity for more liberal design and substantial construction of crest gates.

Spillways

Location—The location of spillways is governed mainly by topographic and foundation conditions and type of dam. Often questions of cost and economy may influence the location. These factors will also determine whether the spillway shall be located on or separate from the dam. The siphon type of spillway is usually located in the main dam structure.

In many cases it may be desirable to locate the spillway away from the main dam because of the erosive action of the overpour. In the case of storage reservoirs this is often possible because many storage dams are built to the same height as the surrounding ridges, where a saddle may be found through which the spillway can be constructed. If no such saddle exists, it becomes necessary to blast a spillway channel out of the rock adjacent to the dam.

At the Davis Bridge dam of the New England Power Company and the Gibson and Owyhee dams of the United States Reclamation Bureau, circular, funnel-shaped spillways were constructed. The spill is designed to discharge into a vertical shaft, which is connected directly to a concrete-lined tunnel. The Davis Bridge spillway is controlled by flashboards which may be removed during floods by tripping a latch. The Gibson spillway is not gate-controlled, but provision has been made in the design so that drum gates may be installed at some later date, thus increasing the storage capacity by 15,000 acre-ft. without raising the crest of the dam. The Gibson shaft and tunnel are 29.5 ft. in diameter and have a capacity of 50,000 sec.-ft. The Owyhee dam is controlled by a ring gate. The shaft has a diameter of 22.5 ft., while that of the tunnel is 22 ft., giving a capacity of 30,000 sec.-ft. when the lake is at its normal level.

Where the spillway cannot be placed on the dam and no natural site is available, the side-channel spillway often is used, as at Don Pedro, Arrowrock, McKay and Tieton dams. This type of spillway often effects a saving in excavation and the spill is discharged well away from the dam.

For diversion dams the problem of separating the spillway from the main dam becomes more difficult for the following reasons: (1) The dam usually is low and the topography of the surrounding country does not as a rule offer a suitable site; (2) the diversion dam usually is located lower down the stream, has a greater drainage area above it and has to pass greater floods than the storage dam. Therefore, it becomes difficult to construct economically a separate spillway, owing to the larger dimensions required, and recourse is made to an overpour diversion dam. The relatively smaller height of diversion dams fortunately lends itself to the crest type of spillway.

Where the spill is over the crest of a masonry dam the normal seasonal flood should be confined to the center of the structure, where the excess energy may be dissipated in a stilling basin. The stilling pool may be either natural or artificial. To obtain additional spill capacity for the exceptional flood, gate openings may be provided on each side of the center and used only during such floods. This will protect the abutments of the dam from continual seasonal wear.

Much study has been given to the design of dam aprons to prevent erosion of the foundation at the toe. The Conowingo, Norwood and Pit River No. 3 and No. 4 dams are notable examples of apron design based on experimental research. An auxiliary dam was constructed downstream from the

---

Publication No. 289-84, Serial Report, Hydraulic Power Committee.

main Martin dam, forming a pool, or cushion of water, 22.5 ft. deep. This pool is designed to destroy the energy of the water flowing over the portion of the spillway which will be used normally.

Formulas and Coefficients—A spillway of the simplest type consists of an unobstructed overflow, the water rising and spilling over the crest as the flow increases. There is a great divergence of opinion regarding the coefficient of discharge for the usual spillway crest. It is the common opinion that 3.33 is too low a value for "C" for spillways of any appreciable depth. As pointed out in *Engineering News-Record,* Vol. 99, No. 4, a large coefficient is found because the depth of flow over the weir usually is measured too close to the crest. If the head is measured at the proper distance upstream so that the velocity head is negligible the formula for discharge may be expressed as:

$$Q = 3.087\ L\ H^{3/2}$$

Where Q = discharge in sec.-ft.
H = head on crest in feet (measured at a point above drop in nappe).

W. F. Martin formula deduced from stream gaging of the U. S. G. S.; *Engineering News,* Sept. 29, 1910, p. 321:

Merced Dam .... $Q = 2.491\ L\ H^{1.77}$
Austin Dam .... $Q = 3.196\ L\ H^{1.59}$
Yakima Dam .... $Q = 3.110\ L\ H^{1.65}$
La Grange Dam .... $Q = 3.088\ L\ H^{1.5}$

If the formulas are recomputed to show the variation in the value "C" in the formula $Q = CLH^{3/2}$, the results given in Table I are obtained. With the exception of the La Grange dam, which is curved in plan, the coefficient increases as the head increases.

TABLE I

VALUES OF "C"

Head, ft.	Merced Dam	LaGrange Dam	Austin Dam	Yakima Dam
0.5	2.065	3.088	3.003	2.803
1.0	2.491	3.088	3.196	3.110
1.5	2.780	3.088	3.315	3.305
2.0	3.003	3.088	3.402	3.451
2.5	3.190	3.088	3.473	3.568
3.0	3.352	3.088	3.524	3.668
4.0	3.623	3.088	3.620	3.829
5.0	3.849	3.088	3.694	3.960
6.0	4.041	3.088	3.754	4.071

The following values of "C" were found by current meter measurements of the flow over the spillway of the Sherman Island plant of the International Paper Company. This spillway dam is built in the form of a horseshoe and is described in detail with the plan and profile shown in Fig. 2 and 11, respectively, of the paper by H. de Parsons in the *Transactions A. S. C. E.,* Vol. 88, 1925.

H	C
0.5	4.26
1.0	3.39
1.5	2.99
2.0	3.19
2.5	3.34
3.0	3.52
3.5	3.66
4.0	3.79
4.5	3.90

In designing the spillway for the Grand Lake dam, Newfoundland, the formula $Q = CLH^{1.5}(1 - 0.05\ n\ H)$ was used to calculate discharge. The crest was favorable for flow, and the piers were thin and pointed. The coefficient "C" varies from 3.30 to 3.90 with heads from 1 ft. to 10 ft., and "n" denotes the number of end contractions.

Discharge measurements were made on the spillway of the Keokuk dam to determine an accurate spillway rating. These studies were supplemented by tests on a laboratory model. Volumes of flow averaging about 4000 sec.-ft. were measured in the 30 ft. of spillway width with the normal operating head of 10.8 ft. It was found that opening the gates adjacent to the spillway where the water was being measured had a very marked effect on the discharge coefficient, tending to increase the discharge for a given head. In the formula $Q = CLH^{1.5}$, the coefficient "C," for the normal operating head of 10.8 ft., varied from 3.71, when a single spillway was discharging, up to 3.90, when many spillways were discharging. The gagings also showed clearly that with a crest unobstructed by piers, "C," for a 10.8-ft. head, increased to 4.00.

The experiments on the laboratory model duplicated the results observed at the dam with remarkable reliability. Experiments were performed on the model when its surface was both smooth and rough, and with and without a fill of sediment upstream from the dams. Results showed that the relative amount of friction caused by the varying surface conditions of the model was of small significance.

The effect of piers upon discharge is best estimated by considering that each pier causes end contraction, thus more or less diminishing the effective length of the spillway crest, depending on whether the upstream nose of the pier is rounded or abrupt. The Keokuk tests showed that extending the pier nose upstream, or giving it a tapered form so that it attained its full thickness a short distance downstream from the highest part of the spillway crest, increased the discharge. The recommended reduction for each contraction, verified by the Keokuk tests, is 0.04 H for sharp-nosed piers and 0.1 H for thick, blunt piers.

Crest Regulation

Crest regulation is necessary where it is desired to keep the pond level as high as possible during periods of low or moderate stream flow (either to gain additional storage or additional head) and at the same time to allow flood flows to pass without raising the pond level to a dangerous height.

FIG. 1—FLASHBOARD SPILLWAY, LAKE FORDYCE DAM, PACIFIC GAS & ELECTRIC CO.

For cases where water is very valuable it is essential to adopt a type of control that is tight and will not waste the flow during periods of drought. For rivers containing much ice or a large amount of debris during floods, the crest must be unobstructed or provided with piers that are sufficiently far apart to prevent stoppage. It is obvious that the need for close control is greater in low-head developments than in high-head plants because, for the latter, a few feet variation of head affects the output a relatively small amount. Devices that only partly control the fluctuations frequently are used since they are relatively less expensive, but the tendency is toward more complete regulation of diversion and storage reservoirs.

Flashboards, Needles and Stop Logs—Flashboards ordinarily are used on storage reservoirs to conserve water, but they are not adaptable for flow regulation. They are put in place on the spillway crest to catch the last of the excess runoff and at such time as the inflow to the reservoir about equals the draft therefrom.

Where the dams are of concrete and can stand a slight overtopping, the spillway is flashed to the height of the dam. If the dam is of rock-fill, a minimum freeboard of about 3 ft. is allowed, and if of earth, a minimum of 5 ft. or more is maintained. Gates for controlling spillways for rock-fill or earth fill dams should be of positive action, as the failure of the dam by overtopping would follow the failure of the gates to function when needed in an emergency. Where lake tenders are in constant attendance, the feature of positive action is not of such importance, providing it is possible manually or otherwise to open the gates under all circumstances. Many old rock-fill and earth dams in California are protected by flashboard spillways and have given years of continuous service. These spillways have been zealously watched during the run-off season, and care is taken in placing the flashboards to be certain that the end of the run-off peak has been reached. In some emergency cases it has been necessary to use dynamite to remove the flashboards quickly, when an unexpected flood peak occurred,

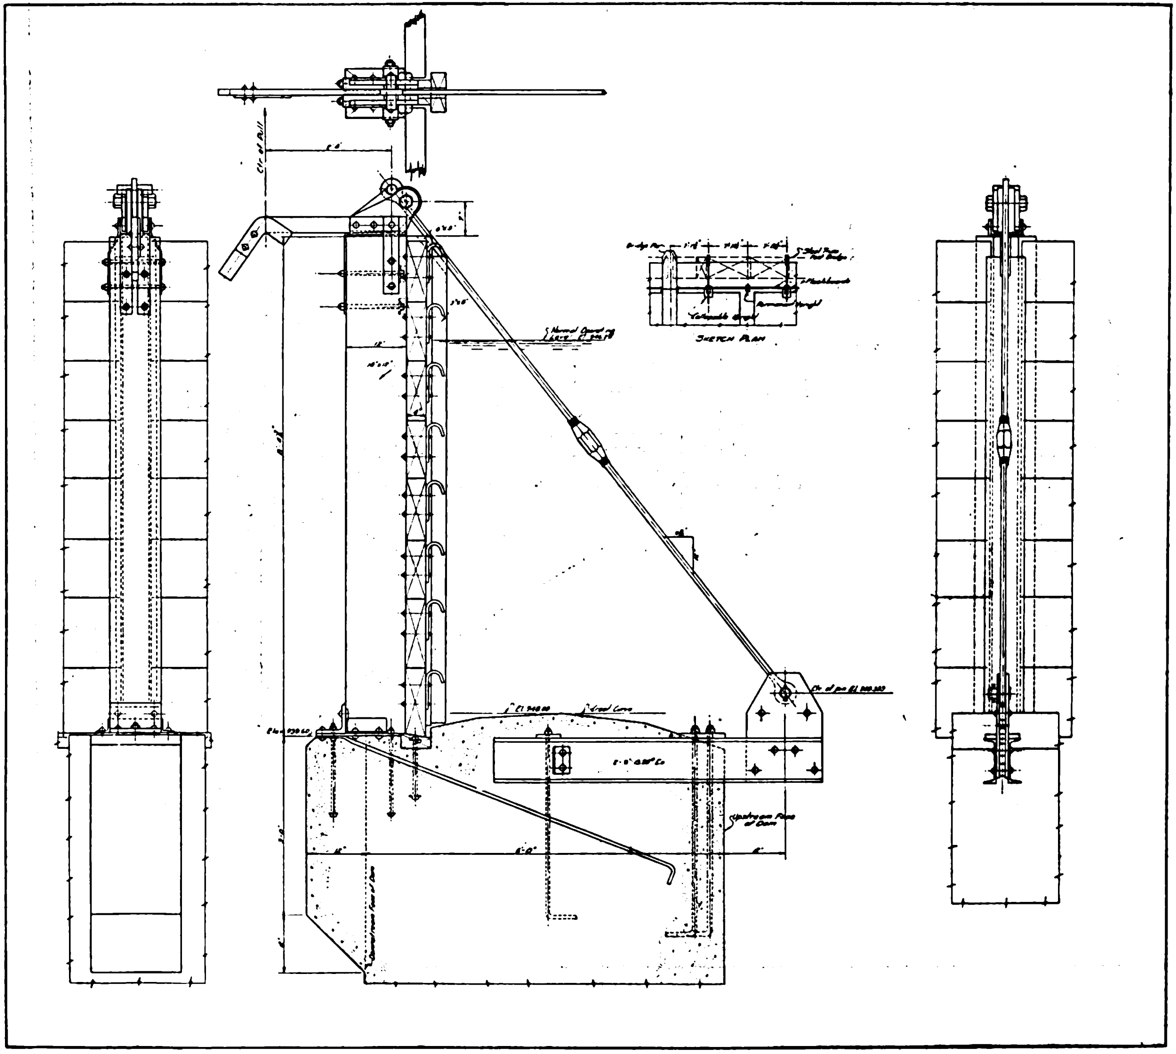

FIG. 2—COLLAPSIBLE FLASHBOARD, KERN CANYON DAM, SAN JOAQUIN LIGHT & POWER CORP.

or to remove debris which threatened to choke the narrow spillway openings. In that case it usually is impossible to replace the flashboards, and the upper part of the reservoir storage is lost for that year.

On diversion dams the normal use of flashboards is to cheaply increase the head on the plant, and they must be supplemented with more easily operated gates for the regulation of flow.

A simple type of spillway where the flashboards are adjusted by hand is shown in Fig. 1. In this design the walkway is placed on the opposite side from the A-frame support. This arrangement permits the line of flashboards to be located closer to the spill lip than in the usual type. When the openings are partially flashed, the sheet of overflowing water then will clear the spill crest. The flashboards rest against wooden shoulders fitted and bolted to the upright steel members of the frame. The flashboard openings are limited to 6 ft., the maximum size one man is considered capable of handling.

The spillway for the Crane Valley rock-fill dam of the San Joaquin Light & Power Corporation is a concrete structure consisting of four bays, each 17.6 ft. long and separated by 2-ft. piers. The crest, which was formerly controlled by flashboards, has been reconstructed to insure more positive control. Manually operated radial gates have been fitted in two bays. These will serve for all ordinary regulation. The other two bays are controlled by collapsible flashboards, three sets being placed in each bay in H-column supports. The boards are normally added or removed by hand. In emergency, when the flow cannot be handled by the two radial gates, a link device on top of the collapsible supports, which are hinged at the bottom, can be tripped, thus allowing all the flashboards to go out. When the emergency has passed, the collapsible supports are erected again and new flashboards placed. A study of runoff and operating records indicated that the possibility of having to trip out the flashboards to take care of an emergency flood was very remote. If conditions were otherwise the arrangement would not be considered satisfactory.

The forebay pond of the Kern Canyon plant of the same company is controlled by collapsible flashboards, as shown in Fig. 2. Ordinary crest regulation is maintained by adding or removing flashboards by hand. This is accomplished by engaging hooks on the flashboards in an iron yoke fastened to a long handle. It is necessary to use a chain block supported from the steel truss spanning the dam for pulling the lower boards. In emergency, the device on top of the collapsible posts can be tripped, thus allowing all the flashboards to go out. The boards and wooden posts are prevented from being washed away by chains which fasten them to the I-beam posts. When the emergency passes, the collapsible posts are erected again and the flashboards replaced.

The Big Bend diversion dam of the Great Western Power Company is provided with 10-ft. needles to increase the pondage and head during the low-water season. The length of the arched crest is 330 ft. The 4-in. Oregon pine needles are beveled from 7¾ to 7⅜ in. in width to facilitate removal and are supported on timber frames bolted to angle irons curved to fit the ogee of the dam.

It is proposed to use needles for crest regulation when the Merced Falls dam of the San Joaquin Light & Power Corporation is reconstructed. The 6 in. x 6 in. x 11 ft. timber needles will rest at the bottom on a structural steel angle and bear against the concrete of the dam, while at the top they will be supported by means of an I-beam attached to a structural steel A-frame, as shown by Fig. 3.

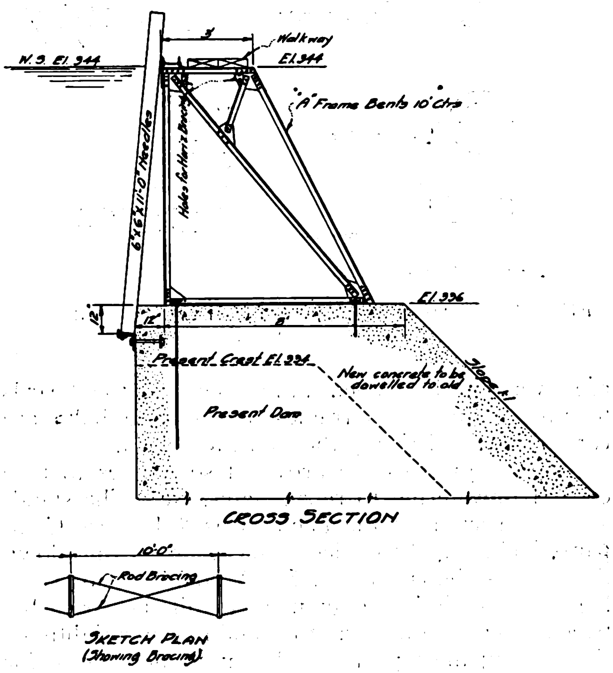

FIG. 3—PROPOSED NEEDLE SPILLWAY, MERCED FALLS, SAN JOAQUIN LIGHT & POWER CORP.

In cold climates ice has caused serious trouble with needle spillways. If ice is allowed to freeze to the needles, they are lifted over the sill when the pond level rises and the diversion will be lost temporarily. Operators are required constantly to prevent ice formation on the needles.

The simplest form of flashboard control consists of a series of panels supported by pins or pipes which are inserted loosely in holes in the top of the dam. The pins are designed to bend over and loosen the flashboards when the water surface in the pond reaches a certain elevation, thus automatically lowering the crest to pass floods. The boards are fastened loosely to the supports and are lost when the supports bend over, unless removed before anticipated high water. Various tripping devices have been used to allow the flashboards to be opened, but not carried away in case of emergency, the Hinckley type being illustrated in Fig. 4.

A variation of the pin support is an A-frame held in place by anchor and release bolts. The bolts are designed to fail in tension when the flashboards

are overtopped. When failure occurs, the boards together with the A-frames and release bolts are carried away, leaving the spillway clean.

Stop-log grooves are provided sometimes to take care of unwatering to repair gates, etc. The standard construction of the Pacific Gas & Electric Company, including the device to facilitate jacking down the logs, is shown in Fig. 5. A double set of stop-logs is used, it being intended to fill the space between them with dirt to obtain water-tightness. Some companies prefer slide or Stoney gates for similar purposes, due to the saving in time in case a unit is out of order, and again because the stop-logs, which may have been provided when the plant was constructed, often are warped and sometimes even used for other purposes. At the Conowingo dam guides were set in the piers to receive a 22.5 ft. x 40 ft. service gate, which will be handled by a gantry crane. This gate is of the fixed roller type and will be used to close the gate-opening when it is necessary to remove one of the crest gates for painting or repairs.

A compressed air system for preventing ice formation along spillway flashboards has been in successful operation since 1925 at the Norway plant of the Indiana Hydro-Electric Power Company. Spillway control works consist of three Stoney gates and an overfall spillway 225 ft. long. This spillway has an ogee section, the crest of which carries 2 ft. of flashboards supported on steel pins. Pond level is generally carried within 6 in. of the top of these boards, and if ice were allowed to form against the boards they would soon be carried away. In the past an open channel had been maintained along the boards by hand chopping, the men standing on the narrow ledge behind the boards.

Hand chopping was hazardous and expensive, and the compressed air system was installed. Air is supplied to a 1¼-in. header pipe by an electric, motor-operated compressor having a capacity of 13 cu. ft. of free air per min. at a pressure of about 10 lb. per sq. in. The air nozzles, which are pipe caps with proper sized holes drilled in them, are spaced on 10-ft. centers; ⅜-in. drop pipes being used to fix the outlets about 20 ft. below the water level. The outlets are graduated in size from 1/32 in. nearest the supply to 5/32 in. at the farthest outlet. An open channel 4 to 8 ft. wide is maintained in front of the flashboards in the most severe weather. No trouble arises from drift ice because the velocity in the pond is very low.

Slide Gates—Sliding lift gates are seldom used for crest regulation because of the large capacity of the hoist required to overcome the friction in raising and lowering. Usually it is found more economical to use fewer piers and to adopt a larger sized gate of a type more easily operated.

FIG. 5—STOP LOG GROOVE DETAILS, PACIFIC GAS & ELECTRIC CO.

The steel gates on Keokuk dam are of the plain sliding variety without rollers. They are 11 ft. high and 32 ft. wide, and operate in slots 14 in. deep in the concrete piers. The gates, see Fig. 6, are finished on the bottom with a timber sill, which makes the water seal against the carefully finished concrete crest of the dam. The gates are raised by electrically operated traveling cranes and are always lifted clear of the water surface, so that a spillway discharges to its full capacity. There are, in all, 119 spillway sections.

Radial Gates—Tainter, or radial, gates are perhaps the type most commonly adopted for use on

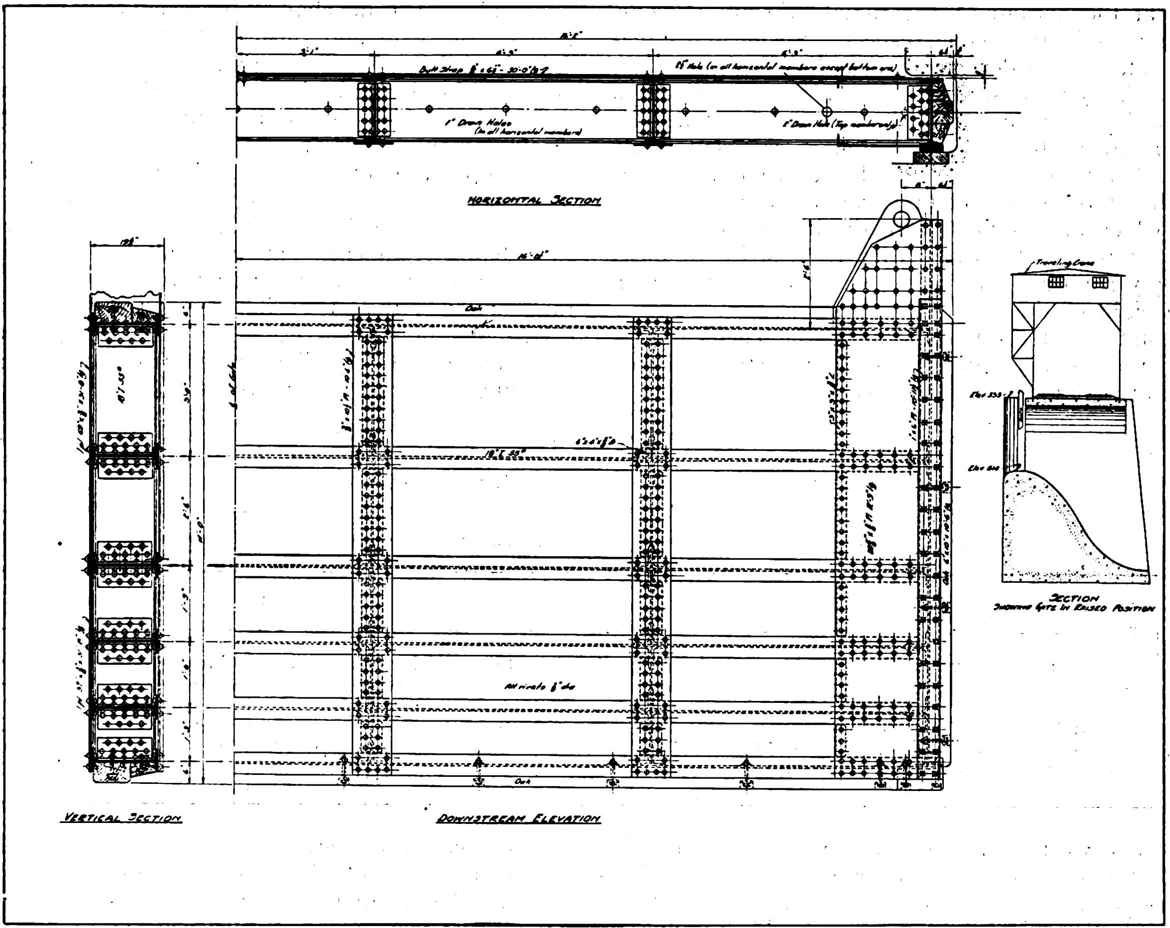

FIG. 6—DETAILS OF STONEY GATES, KEOKUK DAM, MISSISSIPPI RIVER POWER CO.

dams controlling medium-sized drainage areas where floods are not excessive.

In general radial gates for large hydro-electric or irrigation developments must be designed for the particular use to which they will be put. Manufacturers' standard sizes may be obtained in stock from 4 ft. wide x 3 ft. high to 12 ft. wide x 7 ft. high. Where stock sizes and details are applicable some economies may be effected by their use instead of special designs.

Operating mechanisms vary from the individual hand-hoist for the smaller sizes to motor-operated hoisting cars where a series of large radial gates are installed side by side. In either case the gate is lifted by ordinary plough-steel cables, special flat plough-steel cables, or hoisting chains which wind on drums. Where very large chain is used, it may be preferable to pass it over a toothed sheave and permit it to pile up on the floor. Two sources of power are desirable to insure continuity of supply. Auxiliary gas engines generally are considered undesirable. Hand power should be provided wherever practicable. Ordinarily no mechanical effort is required to lower a radial gate, the weight being sufficient to overcome friction.

The introduction of a worm-gear in motor-operated lifting mechanism is highly desirable to safeguard against a sudden power shutdown and dropping of the gate. Care should be taken, however, to avoid high-speed worm-gear reductions; much trouble has been experienced by heating of this type of drive with resulting binding and cutting.

Radial gates may be made practically watertight if care is used in setting and adjusting the gate on its bearings and in selecting the type of side and bottom seals and in setting them. The usual side seal is a piece of rubber belting bolted to the upstream face of the gate and held against a rubbing surface on the side wall or wall guides by the pressure of the water. Rubber side seals range from 6 in. wide, 3-ply strips for heads up to 6 or 8 ft. to 7 in. wide 8-ply strips for heads up to 20 ft. The rubbing surface generally is a channel-beam curved to fit the face of the gate and flush with the side walls of the water channel. The bottom seal for gates with wood faces frequently is a wooden sleeper flush with the bottom of the channel and against which a special bearing block on the bottom of the gate sets.

Wood sills are likely to be bruised by ice or logs shooting under the gate as it is being opened. It is advisable, therefore, particularly in large installations, to use an iron or steel sill. If a small amount of leakage is not a serious objection, the steel knife edge at the bottom of the radial gate offers some advantages in the above respect. Such an installation entails considerable care and difficulty in setting. A more desirable type of bottom seal is a double layer of rubber belting securely fastened on the upstream bottom edge of face and extending somewhat beyond it. These layers fold under the weight of the gate and press against a channel-iron seat which also is flush with the bottom surface of the masonry. The layers vary from strips of 3-ply to 5-ply rubber, 4 in. to 5 in. wide, depending upon the weight of the gate.

Results of tests to determine the coefficient of friction of rubber belting on structural steel and concrete are tabulated in Table II.

TABLE II
FRICTION COEFFICIENT OF 5-PLY RUBBER BELTING

Load Lb. per sq. in.	New Structural Steel				Rusty Structural Steel				Concrete			
	Dry		Wet		Dry		Wet		Dry		Wet	
	Start	Move	Start	Move	Start	Move	Start	Move	Start	Move	Start	Move
4	0.52	0.47	0.80	0.80	0.88	0.82	0.88	0.83	0.67	0.65	0.56	0.50
8	0.53	0.50	0.75	0.75	0.79	0.75	0.88	0.83	0.72	0.70	0.70	0.65
12	0.48	0.42	0.73	0.73	0.75	0.73	0.82	0.80	0.62	0.60	0.70	0.63

Results of the various trials were fairly consistent. On steel there is a decrease in the coefficient of friction as the load increases. When the surfaces are wet, the friction is increased evidently due to the vacuum effect.

Bullards Bar dam of the Pacific Gas & Electric Company is equipped with radial gates for the regulation of spillway (see Fig. 7). There are 19 gates each 10 ft. wide x 20 ft. long. These gates were designed for an existing dam in which journal-box holes were already provided. A county roadway over the gate openings made the design difficult. Chain boxes were set in the concrete roadway in which the excess chain may be stored when the gates are lifted, so that obstruction to traffic may be avoided. These gates were designed to give a maximum free opening when lifted in order to permit legs and debris to pass without striking the framework. In March, 1928, a flood of 57,000 sec.-ft. was passed, with a depth of water of 13.8 ft. on the crest. No damage was done to the gates or dam. Each gate journal boxing was made separate to permit the gates to be adjusted independently. The gates are motor-operated from a hand-drawn dolley car. Each gate weighs about 8500 lb.

Regulation on the Kerckhoff Diversion dam of the San Joaquin Light & Power Corporation is accomplished by 14 radial gates 20 ft. wide x 14 ft. 4 in. high. The piers on the crest vary from 1 ft. 10½ in. to 3 ft. 9 in. thick. They are approximately 21 ft. high and are spanned by a reinforced concrete operating platform 8 ft. wide provided with an iron railing for protection. The rubbing surface for the side seals is a 6-in. channel-beam curved to fit the face of the gate and flush with the side walls of the water channel. Twelve-in. stop-log grooves are provided in the piers in front of the gates; these are used only in case of an emergency or if gate repairs become necessary.

The operating track is of 50-lb. rail imbedded in the concrete on a 36-in. gage. Slots 6 in. x 1 ft. 10 in. are provided in the platform through which two chains from each gate pass up to be engaged by the operating mechanism when it is desired to raise or lower the gates. The gates are operated by a traveling hoist (see Fig. 8) using electric power from an overhead trolley system for hoisting and traveling. In case the power supply were cut off, the hoist can be operated by hand. The gates, which may be used at a maximum head of 14 ft., give very little trouble from leakage and are easily operated. Some little trouble was experienced at first by the chains breaking. This was eliminated by the use of heavier chains. The gates are designed to withstand the normal pressure due to a maximum head of 19 ft. plus 25 per cent for impact. The weight of each gate is approximately 14,500 lb.

Crest regulation at the Prospect dam of the California Oregon Power Company is accomplished by steel radial gates. The gates are operated through remote control from the power house. Hand control is provided for emergency use. In addition, slide gates, or undersluices, are interlocked with the radial headgates, it being expected that the radial spillway gates need be operated only to care for flood discharge. Hoist chains are of extra-strength steel, but it is thought that an equalizer between lifting chains would work to advantage. There is a small roller at each upper corner of the gates to prevent binding during raising. The shaft of the hoisting drum is placed on an inclined plane to reduce the angle between the hoisting chain and the gate during the process of lifting. All motor-operated gates are provided with protective relays.

The pond level of the Chippewa Falls plant of the Northern States Power Co. is regulated by 13 radial gates, each 40 ft. long and 13½ ft. high, having their tops normally 6 in. above the flow line. These gates have rubber seals at the sides, moving in grooves formed in the piers, and when lowered they seat on 8 x 10-in. oak sills imbedded in the crest of

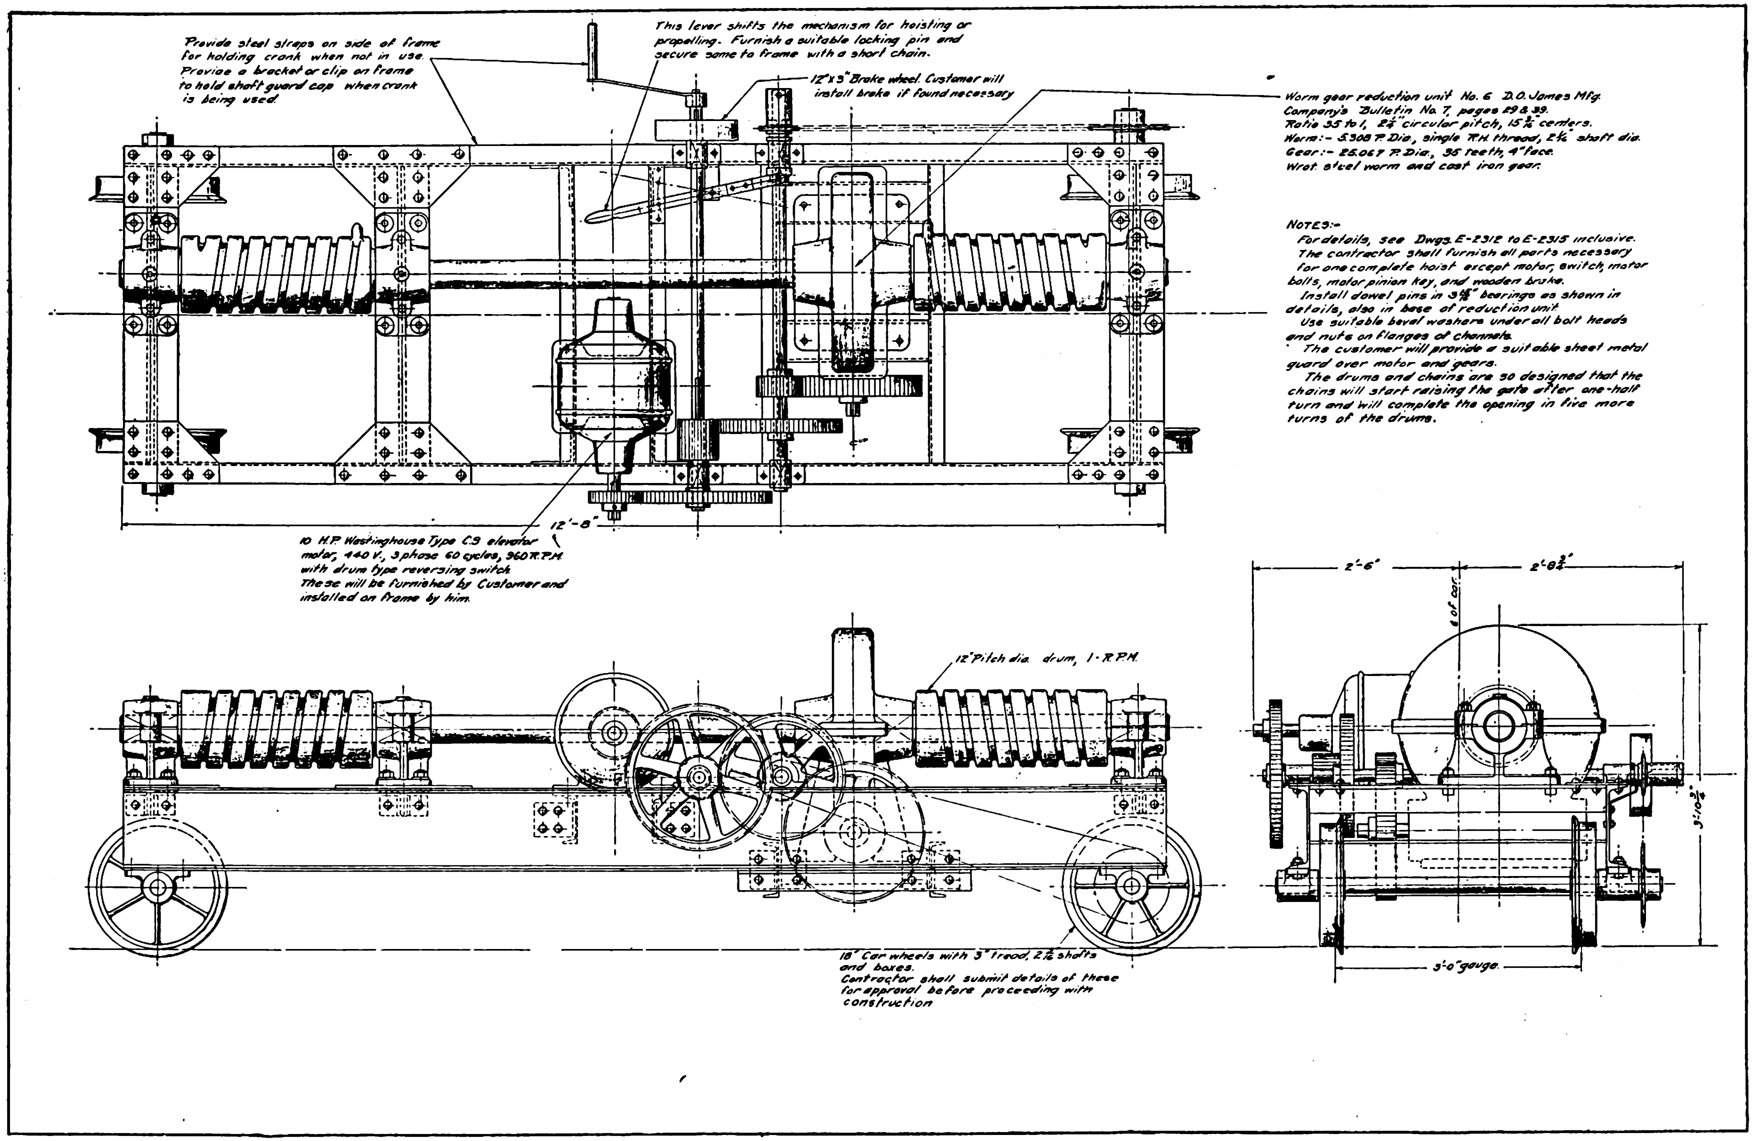
FIG. 7—RADIAL GATES FOR BULLARDS BAR DAM, PACIFIC GAS & ELECTRIC CO.



Provide steel straps on side of frame for holding crank when not in use. Provide a bracket or clip on frame to hold shaft guard cap when crank is being used.

This lever shifts the mechanism for hoisting or propelling. Furnish a suitable locking pin and secure same to frame with a short chain.

12"x3" Brake wheel. Customer will install brake if found necessary

Worm gear reduction unit No. 6 D.O. James Mfg. Company's Bulletin No. 7, pages 29 & 39.
Ratio 35 to 1, 2¼" circular pitch, 15$\frac{9}{16}$" centers.
Worm:- 5.308 P. Dia., single R.H. thread, 2$\frac{7}{16}$" shaft dia.
Gear:- 25.067 P. Dia., 35 teeth, 4" face.
Wrot. steel worm and cast iron gear.

NOTES:-

For details, see Dwgs. E-2312 to E-2315 inclusive.

The contractor shall furnish all parts necessary for one complete hoist except motor, switch, motor bolts, motor pinion key, and wooden brake.

Install dowel pins in 3$\frac{15}{16}$" bearings as shown in details, also in base of reduction unit.

Use suitable bevel washers under all bolt heads and nuts on flanges of channels.

The customer will provide a suitable sheet metal guard over motor and gears.

The drums and chains are so designed that the chains will start raising the gate after one-half turn and will complete the opening in five more turns of the drums.

10 H.P. Westinghouse Type C.S elevator motor, 440 V., 3 phase 60 cycles, 960 R.P.M. with drum type reversing switch. These will be furnished by Customer and installed on frame by him.

12" Pitch dia. drum, 1·R.P.M.

18" Car wheels with 3" tread, 2$\frac{7}{16}$ shafts and boxes. Contractor shall submit details of these for approval before proceeding with construction

the dam. Because of the great length of these gates it would be difficult if not impracticable to place ordinary stop logs to shut off a gate for inspection or repair. Therefore, a 40-ft. steel frame is provided which can be handled by a derrick and lowered into guides in the piers, stop logs being then placed to fill the panels in this frame or emergency gate.

These large radial gates are equipped for both motor and hand operation by means of machinery located on the operating bridge carried by the piers. For each gate there is a line shaft of practically the same length as the gate. The motor and a speed-reduction unit are located at the middle, while the ends of the shaft are provided with worm gears driving the drums which carry the operating chains attached to the gate. The motors of the two gates nearest the power house are arranged also for remote control from the station switchboard, in order to provide for promptly releasing the excess water in case of loss of load on the plant or the necessity of quickly shutting down one or more of the power units.

Radial gates in which the members are stressed in tension were designed for use at Eagle River, Wis., and are shown in Fig. 9. This rather unusual design was made to economically meet a local situation. Reversed Tainter gates were used so that the hinges could be anchored in the existing piers, thus saving the expense of extending these piers downstream. The bottom seal is made by wedging action of the bottom edge of gate against a structural steel angle set in the concrete of the dam crest.

Tainter gates, 25.5 ft. high and 24.5 ft. wide, were used at the Chickasha plant of the Chickasha Gas & Electric Company. These gates have a timber face and were designed to facilitate transportation and erection in small units. The southern yellow pine facing consisted of 8 x 8-in. timbers at the bottom and 6 x 6-in. timbers at the top of the gate. The edges of the timbers were finished on radial lines to give a watertight fit. The hollow 12-in. diameter hinge pins were placed at the same elevation as the top of the gate in order to give the maximum clear opening when the gates are raised.

Where it is necessary to place the hinge pin at a high elevation to obtain spillway clearance, it is often preferable to counterweight part of the dead weight. This was done at the Echo dam of the U. S. Reclamation Bureau and on the Champlain and other sections of the New York State Barge Canal. The four Tainter gates at Echo dam are 17 ft. high x 18 ft. wide. The hinge pin is 15 ft. above the spill crest. The concrete counterweights are attached to a plate steel extension of the gate frame. The unbalanced weight is raised by a fixed electric motor-operated worm-gear hoist on the operating platform. The Barge Canal gate is 26.3 ft. high x 50 ft. long. The hinge pin is 24.4 ft. above the spillway crest. The gate is partially balanced by concrete counterweights, which are supported by an extension of the gate frame and controlled by a link arrangement.

Tests have been made by the Pacific Gas & Electric Company to determine the lifting forces for radial gates. The results show that the forces varied from 88 to 100 per cent of the total weight of the gates. In all cases, the center of the axles is at the exact center of the line of thrust on the curved gate face.

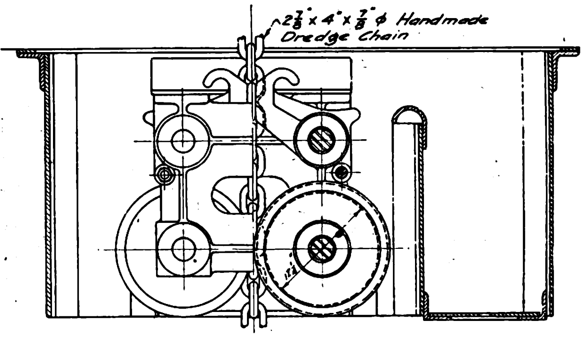

FIG. 10—CHAIN DOG AND SHEAVE FOR TAINTER GATE, BARTLETTS FERRY DAM, COLUMBUS ELECTRIC & POWER COMPANY.

When chains are used for hoisting the radial gates, slotted lock plates may be employed to hold a gate in any position. These plates slip over the chain links and rest on the operating platform. A chain dog and sheave used on the large Tainter gates of the Bartlett's Ferry dam, are shown in **Fig. 10.** The sheave guides the lifting chain and holds it in position so that it can be locked by the dogs when slacked off. The housing of the sheave is set flush with the operating platform and serves as a chain box. Direct braking on part of the lifting mechanism or the use of pawls on the gears to hold the gate in any desired position is not recommended, but under certain conditions may be necessary.

An approximate formula for estimating weights of radial gates was given in *Engineering News-Record,* Vol. 96, No. 12, as follows: "Weight (lb.) = area (34 + 0.114 width x av. head)." The formula is said to give results approximately correct for small gates and about 10 per cent too high for large gates. See Table III for dimensions and weights of radial spillway gates in service.

Sector or Drum Gates—The drum or sector gate has fulfilled the need for a crest gate which will give close spillway regulation by automatic or remote con-

trol and permits large, unobstructed opening for the passage of flood flow. Sector gates have proved to be secure and easy to operate under the most adverse conditions and are not affected by ice or drift. This type of gate has been selected as the standard spillway gate by the U. S. Reclamation Bureau.

In general, drum gates are pivoted on a continuous casting anchored along one edge of the gate recess with pin bearings at approximately 4-ft. centers. The gate is floated up by pressure from underneath and lowered by gravity upon relieving the pressure. One of the earliest examples of this type of gate was installed by H. M. Chittenden on the Osage River about 1896. This gate had a height of 7 ft. and consisted of a sector including 67½ deg. of angle. The interior framing of the gate was made of iron while the covering was of wood.

Details of the 14½ x 68-ft. drum gates installed in the Pit River No. 4 dam of the Pacific Gas & Electric Company are shown in Fig. 11. Operation is not automatic, although the movement of the gates may be remote controlled from the Pit No. 3 power house if desired. It was difficult to find a suitable spring brass for the downstream seal, but the brass seal material selected has given very little leakage in service. Each gate weighs 210,000 lb.

The Southern California Edison Company installed two 12 x 51-ft. drum gates at the Florence Lake dam in 1926 (see Fig. 12). High-water level at Florence Lake is at El. 7327.5 ft. and the reservoir serves to regulate the flow of the South San Joaquin River for diversion to Huntington and Shaver Lakes. The gates may be operated either by automatic or by hand-control. Control apparatus is housed in the end piers.

Both drum gates are alike in structural details and mode of operation. Each gate consists of a watertight, sheet-steel drum, caulked and welded and with a flat bottom and cylindrical sector faces. The drum is built up of ⅜-in. plate riveted over a ribwork on the three sides. A channel imbedded in the concrete by anchor bolts runs along the upstream face of the spillway and forms the foundation for the hinge anchor castings for each gate. Each drum is pivoted upon 14 hinges which are built up to a thickness of about 2½ in. for bearings on the hinge pins. Each hinge anchor is fitted with eccentric bushings to facilitate alignment.

Considerable study was given to the design of seals because the accuracy of automatic control depends upon the amount of leakage past the seals from the pit. Spring brass was used as a seal at the upstream toe of the gate along the hinge casting. The seal at the downstream seat casting and at the downstream end of the side plates consists of 6-in., 8-ply conveyor belting. On the upstream end of each side plate is a hollow recess formed by the legs of two angles. A 3½-in. suction hose in this recess tends to flatten under the pressure of the water and acts as a seal.

The drum rests on the bottom of the pit until water in the lake rises sufficiently to enter the inlet pipe, which is at the same elevation as the bottom of the drum pit. As the lake rises, the drum floats in its pit until it reaches the limiting elevation when it strikes the stop on the gate seat casting. Further rise in the lake level brings the automatic control into operation to regulate the spill. A state of balance is maintained between the lake level and the position of the gate so that the elevation of the lake never

FIG. 12—Drum Gates for Spillway, Florence Lake Dam, Southern California Edison Co.

is appreciably greater than the crest of the drum gates when in their maximum position.

No difficulty is encountered from ice conditions, since the lake is drawn down below the level of the gates during the winter months and the gates remain in their lowered position with no water in the drum pits. Trash and logs are easily passed over the gate crests during run-off season.

Each gate was manufactured in seven sections to facilitate transportation. The sections were riveted together in the field with inside butt-straps; all seams which were not caulked were electric welded. A tolerance of only ⅛ in. in the radius of the downstream face was allowed. All structural steel was specified to conform with A. S. T. M. standards and steel castings to specifications A 27-24, Class B, medium grade, of the A. S. T. M. Hinge pins and hinge anchor bushings were made of forged manganese bronze having a minimum elastic limit of 30,000 lb. per sq. in. Stresses in structural steel were not allowed to exceed 16,000 lb. per sq. in. in tension and 12,000 lb. per sq. in. in shear.

The European type of sector gate differs from the above American type, since it is hinged at the downstream side (see Fig. 13). At Raanaasfos in Norway there are two sector gates each having a length of 164 ft. and a regulating height of 12.3 ft. In a normal year in Norway several million logs are floated down each primary stream. Sector gates may be opened and closed quickly to pass logs which have collected above the dam. The gates are regulated by automatic or by hand control. Seals are of flexible brass. The Raanaasfos gates are not operated in winter, but are kept locked in their highest position. Winter operation is not impossible because the sector gates at the Weser dam at Bremen, Germany, have been operated without difficulty during long periods when the temperaure was as low at —4 deg. fahr. The total weight of each Raanaasfos gate is 232 tons.

Several sector gates, similar in general arrangement to the European type, are in use in New York State, together with two gates on the Chicago Drainage Canal. The two gates most recently installed were built for the Court Street dam of the Rochester Gas & Electric Corporation in 1926. Each gate is 110 ft. long and has an operating height of 11.1 ft. A gate is approximately a 28 deg. sector of a cylinder having a radius of 27.25 ft., built up of a steel framework and hinged at the downstream side. The 6-in. diameter bronze shaft is hollow to allow a heating pipe to be run through it from a central heating plant with a return line through the chamber under the dam near the hinge. This was done to prevent the formation of ice which might hinder the operation of the gate in the winter season. Heating pipes were also inserted back of the plates which form the end of the sector chamber. Rubber belting is used for the end seals. A gate may be locked in its raised position by means of keyed dogs. The weight of each sector is 160 tons, while the hinge, shaft, etc., weigh an additional 103 tons.

Ring Spillway Gates—A radically new spillway gate, a modification of the sector type, was designed and is being constructed for the Owyhee dam of the U. S. Reclamation Bureau (see Fig. 14). The circular spillway is the lip of a funnel formed at the head of a shaft discharging into the diversion tunnel 240 ft. below the tunnel intake. The funnel is surrounded by a structural steel ring gate 12 ft. high and 60 ft. in peripheral length, constituting a floating crest. It is planned to build the gate in 12 shop-riveted segments, to be joined in the field. A needle valve is used for control of the gate. This arrangement follows closely the recent sector gate installations of the U. S. Reclamation Bureau. The spillway shaft has a diameter of 22.5 ft., while that of the tunnel is 22 ft., giving a capacity of 30,000 sec. ft. when the lake is at its normal level.

Roller Gates—The roller gate is a heavy-duty gate which has not come into general use in this country. It consists of a cylinder or trussed sector. The roller has at each end a circular geared bearing which rolls on a geared inclined track laid in a recess in the pier. The gate is lifted by a cable or linked chain encircling the gate near the bearing. A modification of this type is the rolling sector gate of the Washington Water Power Company (see Fig. 15), which utilizes trusses as the main members which carry the water load to the end bearings. The main advantages of the roller gate are the accessibility of the structure when the gate is open and the long, clear widths of spillway openings.

An important feature of the roller gate, of comparatively recent development and application, is the arrangement whereby it can be partially lowered. There are often serious objections to the great wastage of water and loss of head attendant to opening the gates for sluicing out ice or debris. By the new design, the gate may be dropped 1 to 4 ft. below the pond level, which allows ice and other floating matter to pass over the gate. For normal operation the gate is raised to give full required opening underneath.

At the Lewiston, Idaho, development of the Inland Power & Light Company three roller gates were in-

stalled for the control of all ordinary floods. Each gate is 105 ft. long and 18.5 ft. deep. Each consists of 17 cylinders fastened together by field-riveted, milled, butt-strap joints. A hoist mechanism operates a link chain on the driven end of the gate. Two roller gates, each 18 ft. high and 115 ft. long, were installed at Bellows Falls by the New England Power Association. Severe ice conditions are to be expected at this plant in winter, and the roller gate possesses marked advantages over other types of gates where certainty of operation during the cold season is essential.

Many installations of roller gates have been made in Germany and Scandinavia, where they are used for winter regulation as well as during the flood season (see Fig. 16). Electric heating elements installed in a recess back of the end plates keep the gate ready for operation under the most adverse conditions. Logs are not passed under the roller gates. Normal operation is by electric motor, but if the electric energy should fail, the gates may be raised by hand-operated hoists.

Table V gives dimensions of noteworthy roller gates now in operation.

Butterfly Gates—At each end of the Exchequer dam there is a spillway 168 ft. wide equipped with seven vertical-shaft butterfly gates. This type was selected because it was possible to construct the dam with a thinner crest than would have been feasible with the more commonly used type of gate. Operation of the gates is effected by a 20-h.p. motor mounted on a car which moves along the dam crest engaging the several gate-operating mechanisms successively.

The outside dimensions of the gates are: Length, 24 ft.; height, 14 ft., and thickness, 3 ft. The gates are built up of structural steel consisting chiefly of 3/8-in. plates and angles of suitable size and spacing. The gates are hollow except for the internal bracing

and the hollow cast-steel shaft, 24 in. square and 2¼ in. thick, which extends through the center of the gate from top to bottom. To facilitate shipment the gates were made up in the shop in three pieces which were riveted together in the field. The weight of the rotating part of each gate is about 19 tons.

There are no piers between the gates. The rounded ends of adjoining gates fit against each other when they are in the closed position. Leakage is prevented by a brass strip fitted to one end of each gate and arranged so that the spring is pressed tightly against the adjoining gate when in the closed position.

Stoney Gates—The Stoney gate has not met with favor in western United States. This type of gate is used in the southern and eastern states and in Canada, primarily because of its simple design and ease with which it can be operated and kept free from ice in the winter season. The Stoney gate has been used with a depth of water of 50 ft. for openings 50 ft. wide, and for lesser depths for widths up to 80 ft. The gate moves in vertical grooves in masonry piers on trains of rollers. In some cases the gates are partly operated by counterweights amounting to 75 to 80 per cent of the weight of the gates, and partly by powerful gearing arranged to be worked by hand or by power, which serves to raise or lower the unbalanced weight. The counterweights have been omitted from many recent installations, the gates being lifted by gantry cranes. This arrangement is preferable where there are a number of such gates in a spillway.

The Dominion Bridge Company, Ltd., Montreal, Quebec, comments on bedded parts, roller trains and sealing devices as follows:

"In the design of bedded parts, the all-important point to keep in mind is the method and facility of erection, and secondary only to this is the ease of machining and retention of their alignment during handling and when set in place in the field. To adequately take care of these features one must be fully acquainted with conditions at the site and the method to be adopted in placing the bedded parts in their final position.

"As a rule, the best procedure is to construct the mass concrete of the piers first, leaving a void large enough to take the bedded parts with sufficient grouting room behind them, and placing in the forms of the mass concrete sufficient anchors, to which the bedded parts can be readily attached and adjusted for final alignment by the field engineer before the grouting is poured behind them to make a monolithic whole with the mass already set.

"Attempts have been made to set the bedded parts by attaching them to the forms for the mass concrete and pouring the whole of the concrete work with the steel work in place. This has not been very successful up to the present time. In the first place, it must be remembered that the bedded parts are often thirty or more feet in length, and the forming and pouring of the concrete can only be done in suitable lifts of ten feet or so, thus allowing an unsupported length of steel to be standing in the air subjected to warping and deflection while the lower portion of the concrete is being placed. Secondly, it is almost impossible to keep the steelwork in true alignment due to the contraction and expansion of the forms under the varying atmospheric conditions during the operations. In one instance, where the general direction of the dam was north and south, the readings for the alignment of the steel would vary morning and evening, depending on the position of the sun.

"The general idea of placing the steel at the same time as the mass concrete is a good one, and is still being given serious consideration in some quarters, as it allows the whole of the concrete work at that place to be done at one time. However, if it is to be successful the bedded parts should be provided with a very rigid set of temporary bracing which would definitely determine and fix the alignment in all planes, or the bedded parts of adjacent gates should be built as rigid towers, which would be self-supporting during the pouring of the mass concrete. This, of course, means that the order for the gate work should be placed early enough to allow the bedded parts to be on the site before the masonry contractor starts work on this portion of the development.

"Sometimes bedded parts have to be provided for gains already left in the masonry, originally provided for the extension of an existing plant, where there is no provision for anchors and no room left for grouting between the steel and the existing concrete. This is a condition which should be avoided under all circumstances, as it entails an enormous amount of extra work in unwatering and drilling for the anchors and cutting away concrete in places where it is unsuitable for the steelwork. Also, it is almost impossible to obtain an alignment of the steel which will provide a satisfactorily watertight gate. The design of steel work in such cases would have to be specially considered for each installation and generally causes trouble in both shop and field due to a want of rigidity of the member in consequence of the unrestrained room at one's disposal for the placing of the steel.

"Bedded parts should provide for roller or sliding paths, sealing faces for the sides, bottom and top where required, guides for the roller trains where necessary, and both back and end guides for the gate. These provisions should be designed as separate units and the field engineer must be relied upon to place them in their correct relationship to the concrete.

"A better arrangement, however, is to design the whole of the bedded parts as a complete steel unit, definitely spacing the various parts in their correct location and assembling them as a complete frame in the shop for final field alignment by the anchors, additional temporary bracing being used where necessary, the use of such bracing always being an advisable precaution in order to ensure good results.

"Anchors for bedded parts have been made by providing through pipes in the piers, which were set in place during the forming of the mass concrete, and through these pipes were inserted long rod bolts with double nuts at each end to secure the bedded parts in their correct positions. It is, however, a difficult matter to place the heavy and unwieldy bedded parts on the anchors, and the arrangement of such anchors generally provides for adjustment only in one direction.

"A later and better arrangement is to bed, in the mass concrete, angles having the two legs flattened together at the ends, and holes drilled at each end to take independent hook bolts at the required intervals and arranged in such a manner that the bedded parts can be aligned in both planes, necessary holes being provided in the steel to take the hook bolts. These bolts are provided with two nuts for adjustment, or wedge blocks may be provided between the steel and concrete and the bolts tightened against the blocks. This arrangement of anchor and hook bolts has the advantage that the bedded anchor angle does not have to be as accurately placed in the forms, as in the case of the bedded pipes.

"The location of anchors should be so arranged that projecting nuts and ends of bolts cannot by any means foul the gate or moving parts, and it is preferable, if possible, to place the anchors so that the gate and roller trains move in a perfectly smooth gain, as projections are not only liable to foul moving parts under unforeseen conditions, but also form a place where debris, floating objects, and ice can lodge and possibly cause considerable trouble.

"For the same reason the guides for the gates and roller trains should be of smooth construction throughout and places of entry should be well set back, chamfered, or rounded, to permit ease of entry of the gate and prevent any jamming taking place during operation. It might be well to mention here that all conditions should be considered and provided for by the designer, however improbable they may seem to be.

"The earlier forms of roller trains consisted of live steel rollers rotating on bronze pins located in such a manner that the spacing of the rollers is evenly proportioned to the head of water, thus providing a uniform unit pressure on each roller. The bronze pin is supported by steel bars, bar and angle, or angle sides to give a stiffness to the member as a whole, in the direction of the flow of the water, and the sides projecting beyond the face of the roller to form a guide for the train on the edge of the roller path.

"This type is quite satisfactory for low heads and low velocities, and might even be so with head gates where the velocity does not exceed about 10 ft. per second, but with the advent of larger gates and higher heads and velocities it was found necessary to provide a very definite guide to the roller train in both the direction of the flow and at right angles to the same.

"Moving roller paths apply to Stoney roller gates only, since in the case of gates with fixed rollers the path on the gate is dispensed with. These paths, which are usually made of a rolled or forged steel bar, require to transmit the water pressure from the web of the end girders into the rollers, and should act in such a manner as to transmit the pressure uniformly over the face of the roller. To do this under varying deflections of the cross girders of the gate, and in order to provide for any inaccuracy of alignment of the fixed roller paths, it is necessary that the moving path should be capable of equalization over the web of the girder. The best method of accomplishing this is to project the planed edge of the web of the girder beyond the flange angles and plane a groove down the back of the roller path to fit very loosely over the projected web of the girder, so as to restrain the path from any side displacement, and at the same time to allow the path to rock freely on the planed edge of the web.

"The path is then drilled and counterbored for the attaching bolts which are provided with pipe spacers of sufficient length to keep the path from falling off the edge of the web and at the same time allow a reasonable rock to the path.

"Sealing devices may generally be divided into two types: the stanching rod type, and the flat, more or less, spring type. The former are preferable for crest or sluice gates where they will be subjected to severe ice conditions, on account of their greater mechanical strength, while the latter are better for head and all totally submerged gates, where ice conditions are not effective, on account of their greater degree of watertightness.

"In the case of the round stanching rod, the matter of attachment is a most important one. It should be flexible enough to allow the pressure of the water to take the sealing rod up to the sealing faces under all positions of the gate, and at the same time it should be strong enough to resist action from the ice and allow the removal of the ice for winter operation.

"The best method of attachment is by means of a heavy flexible suspension from the upper end, capable of resisting both the upward and downward thrust which occurs when the gate is being operated, but entirely free in the direction parallel to the skin plate of the gate. The rod is restrained within the required limits of flexibility by strong steel retaining fingers placed at intervals along the rod and fastened to the gate by heavy bolts. These fingers and bolts should be made in such a manner that they are not easily damaged by ice and can be cleared of ice without loosening or breaking the attaching bolts. The design of the sealing attachments is one that will bear considerable thought and study.

"The spring type of seal is sometimes made from a thin flat brass strip with a D-shaped brass bar reinforcing one edge, or alternatively, of a thin flat brass strip bent with an offset to keep it away from the face of the gate and allow a space for attaching bolts, also having the front edge bent back to allow practically a line contact with the sealing face under all conditions. The seal is usually attached to the downstream face of the gate in such a manner that the water pressure will force it against the sealing face.

"The above mentioned methods of sealing apply to gates of the Stoney and fixed roller types, and in both cases particular attention should be given to clearance between the moving seals and fixed parts of the bedded members. This clearance should be ample in all positions of the gate and

> should allow for a maximum amount of adjustment of the side rollers, and at the same time provide against any possible chance of the seal leaving or even approaching the edge of the sealing face.
>
> "In the case of gates of the Stoney roller type, the provision of clearances between the seal and the moving roller train should be carefully looked into, and it should be remembered that there is bound to be some relative movement sideways, between the gate and the roller train, the maximum of which should also be taken into consideration and duly provided for.
>
> "The question of the effect of deflection of the top girder of the gate, under maximum head, on the top seal should be taken into account when considering the clearance between the top seal and the lintel of the bedded parts and concrete above this lintel.
>
> "The bottom seal of the gate is generally formed by the fit of the planed sill beam bedded into the concrete and forming one of the members of the bedded parts. In cases where the gate is too wide to make this fit by planing, the sealing bar has to be chipped to fit, or the sill beam may be attached to the gate by temporary lug angles and wedged firmly against the bottom of the gate after it is in place, and then the concrete poured and allowed to set before the clips are removed and the gate lifted.
>
> "In some cases the necessary sealing is obtained by means of a heavy planed oak beam attached to the web of the lower beam, in which case care should be taken to see that the sealing edge is in reasonably close vertical alignment with the sealing face of the vertical seals to prevent leakage at the corners. A further precaution of a hemp rope or rubber hose partially bedded into a groove in the sealing timber will often assure a more watertight seal at this point."

Three Stoney gates are provided to control the spillway of the Stoney Gorge dam, of the United States Reclamation Bureau, an Ambursen type structure (see Fig. 17). Each gate is a 30 x 30-ft. structural steel leaf of the overflow type. The gates are operated by large screw stem hoists driven by electric motors. The gates are mounted on a 45 deg. slope and slide down the upstream face of the dam in opening. The overflow type of gate was adopted on account of the large amount of drift carried by the river during the flood stage; and also on account of the smaller head required to pass corresponding floods than with the underflow type of gate.

The north spillway of the Guernsey dam, also of the U. S. Reclamation Bureau, is controlled by an electrically operated Stoney gate 50 ft. in height and, 54.62 ft. wide, which closes a clear opening 50 ft. in width (see Fig. 17). The gate leaf, weighing 434,000 lb., is counterweighted by concrete blocks, each counterweight weighing 187,000 lb.

This gate leaf is built up of twelve plate girders 6 ft. deep, laid horizontally, with diagonal bracing, and covered on the water side by a 9/16-in. skin plate. The sliding friction is taken care of by six sets of rollers on either side, riding on an H-beam. Any deflection in the girders that would tend to throw the rollers out of plane is taken care of by the flexibility of the web of this H-beam track. The side seals on the upper side of the leaf are of brass pipe moving on lugs riveted to the skin plate. This pipe is forced by the water pressure against the 6 x 6-in. seal angles embedded in the concrete.

The crest gates of the Conowingo dam are of the Stoney type, 22.5 ft. high x 40 ft. wide, with timber seals at the bottom and rubber-covered staunching seals at the sides (see Fig. 18). Fifty crest gates are provided. Upstream from the crest gates additional guides are set in the piers to receive a service gate. This gate is of the fixed roller type and will be used to close the gate opening when it is necessary to remove one of the crest gates for painting or repairs.

The crest gates will be handled by gantry cranes. Three cranes are provided for this purpose, and also for handling the sectional head gates and trash racks. For handling the crest gates the cranes are equipped with special lifting beams, which are arranged for an operator to ride when he operates the locking device and attaches it to the gates. When the gates are raised to their open position they will be held in

place by means of pawls engaging suitable stops on the ends of the gates, thus permitting the crane to move on to the next gate. The duty cycle of these cranes requires about 9 min. to lift a crest gate.

The Stoney type of gate with roller trains is used by the Laurentide Power Company, Ltd., for spillway regulation. The roller trains move vertically when the gate is moved and are held in position laterally by a steel angle bolted to the concrete structure. Originally this extended from the bottom of the roller train at its closed position to the top elevation of the gate when closed. As a consequence, when a gate was open the swirl of water passing through tended to loosen the fastenings of these guide angles. The remedy was to change the location of the guide angles by raising them so the lower end would not be exposed to this action of the water.

These gates have bronze seal rods vertically attached at each end. They are loosely attached and are forced into their sealing position by the pressure of the water. They are very effective, but have occasionally become loosened when it became necessary to operate gates in the winter with several feet of ice on the pond.

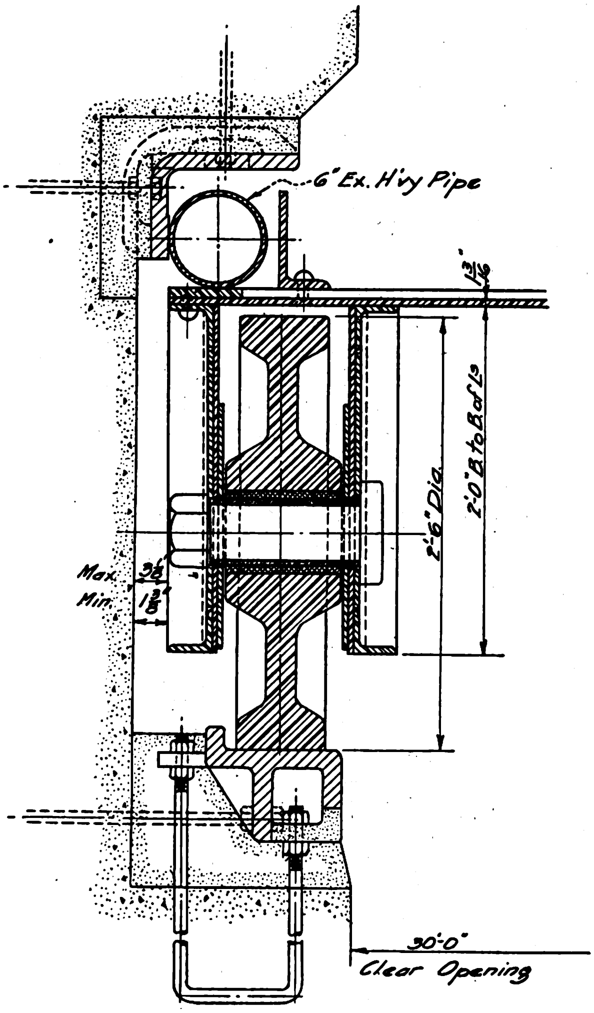

FIG. 19—Guide and Seal for Stoney Gate, Lock 18, Alabama Power Co.

The practice has been to paint these gates about every third year, but for the most part this has been for improvement in appearance rather than due to necessity on account of rusting. Practically speaking, rusting need not be taken care of more often than once every five years. An important cause for rusting is abrasion of the skin plate due to rise and fall of the ice cover on the pond. The resulting abrasion is not serious, and merely removes the paint here and there, especially on the rivet heads. A high grade of red lead paint is used.

Fig. 19 shows details of the Stoney gates used by the Alabama Power Company with the roller train and sealing arrangement. The gates are operated by a traveling hoist. The Lock 18 spillway gates are 18 ft. high x 30 ft. wide.

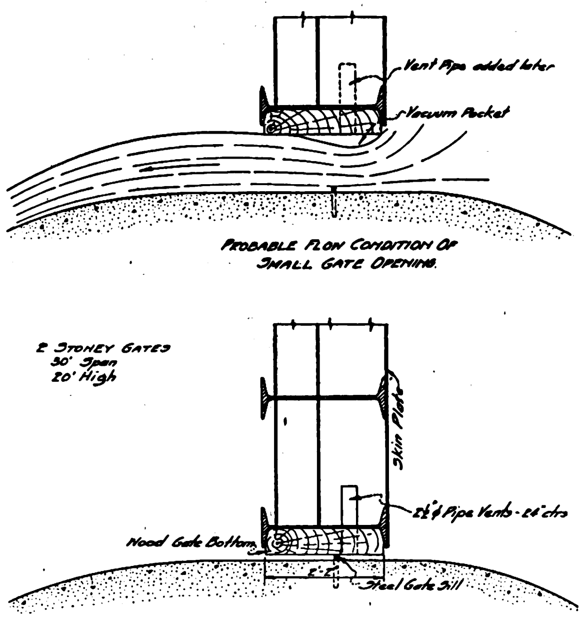

FIG. 20—Method of Eliminating Vibration in Stoney Gate, Interstate Public Service Co. of Indiana.

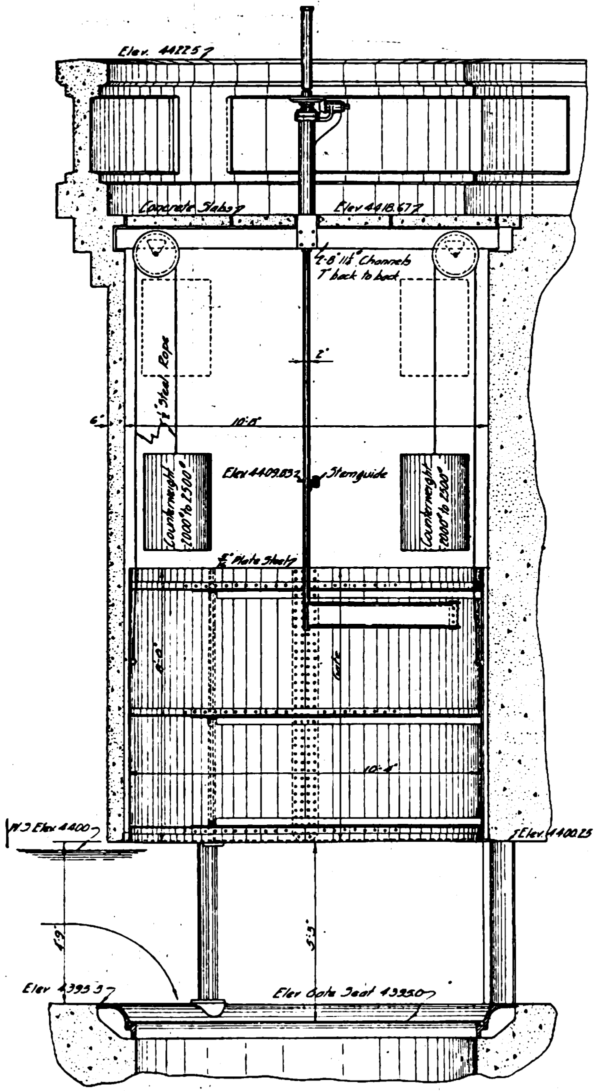
Fig. 20 shows the methods of venting two 20 x 30-ft. Stoney gates of the Interstate Public Service Company of Indiana, to eliminate vibration due to vacuum conditions. These gates have a flat, wooden member, 26 in. wide, which is attached to the bottom I-beam. This wood bottom seats against a thin steel sill embedded in the concrete of the spillway crest. At small gate openings violent vibration of the gate occurred, caused by the alternate making and breaking of the vacuum under the flat gate bottom. The vibration appeared to be concentrated at the center of the gate. To relieve the vacuum, vent holes on 24-in. centers were cut through the bottom I-beam and wood bottom and short lengths of 2½-in. pipes were welded into the holes. One of the gates was provided with 10 holes in the central portion, and later the other gate was provided with only 6 holes. This number proved to be sufficient, and no further trouble due to vibration has been experienced in either gate. It is suggested that trouble from vibration could be avoided by limiting the width of bottom to 12 in.

At another installation of the same company consisting of three 22 x 30-ft. Stoney gates, the sealing device was made up of 3-in. rubber tubing held loosely in the angle between the skin plate and the gate pier. The tubing was kept in place by clips loosely fitted and attached to the gate at 5-ft. centers. After about two years' service it was found that the tubing had stretched so that it buckled away from the joint and no longer served its purpose as a seal. Since the tubing was in good condition, a 2-in. iron pipe was inserted in it to prevent buckling. The pipe rested on a shoe at the bottom and was loosely held in place at the top. The modified seal was sufficiently flexible to serve its purpose.

Cylinder Gates—The Elephant Butte Dam spillway contains four cylinder gates for flood regulation (see Fig. 21). Each consists of a boiler-plate cylinder 10.3 ft. internal diameter and 8 ft. high mounted within a cylindrical concrete tower. Each cylinder is provided with two counterweights and is raised by means of a hand-operated hoist at roadway level. A single seat is provided at the bottom, and the clearance between the cylinder and the concrete is kept at a minimum to prevent leakage over the top of the cylinder in case of high water. The lower seat ring is an iron casting set in the concrete and carries three cast iron posts which help to support the concrete tower. Each gate discharges through a curved concrete draft tube leading under the spillway weir.



SECTION C-C

FIG. 21—CYLINDER GATE AND SPILLWAY, ELEPHANT BUTTE DAM, U. S. RECLAMATION BUREAU.

Siphon Spillways—The siphon spillway is a device for discharging water over a dam. It utilizes the available head to produce a higher velocity of flow than would be attained at an overflow weir, thus increasing the discharge. The siphon spillway has many advantages over any other type of spillway control apparatus up to a required capacity of 200 sec. ft. per ft. of crest length.

The evident advantages of this type of spillway are as follows: The action is entirely automatic. Priming takes place quickly so that the full capacity of the spillway is effective in an extremely short time, varying from 5 to 10 sec. to 2 or 3 min. for extremely large siphons.

The fluctuation of the water surface above the normal reservoir stage is restricted to a comparatively small range. The siphon type of spillway, owing to its close regulation of the reservoir level, allows the spillway crest to be raised considerably above what would be the case in a free overflow type of spillway and therefore makes available additional storage capacity at the top of the reservoir.

Under the limitations of discharge per lineal foot of crest length of spillway, as noted above, the siphon spillway can be built in approximately from one-half to two-thirds the area required for almost any other automatic or non-automatic type of spillway. In locations where freezing conditions obtain, consideration should be given to the possibility of the formation of ice in the siphon due to a small amount of water washing over the throat.

At Huntington Lake Dam the Southern California Edison Company provided a battery of seven siphon spillways (Fig. 22) which would prime at different elevations of the lake surface within the normal range of operating levels. Their combined capacity is 550 sec.-ft. The siphons are similar in construction, but the throat crests are at slightly different elevations and the downstream legs vary from 15 to 22 ft. The air-control passage running from the face of the dam to the upper throat of each siphon is controlled by a slide gate operated from the top of the dam. By varying the height of the gate the elevation at which the siphons prime is thereby adjusted. Priming is aided by a "back-pressure" control which allows the air in the top of the siphon to discharge quickly. The siphons are constructed of reinforced concrete.

Huntington Lake is kept near the normal operating level in order to keep the effective head on the Big Creek No. 1 power house as high as possible. Very little water is spilled from the reservoir because any surplus water can be diverted to Shaver Lake through

the Huntington-Shaver conduit, which was recently completed. In order to prevent waste of water and damage downstream by the spilled water, the siphon spillways have been modified to act as free-flow spillways by simply adding an air duct to prevent priming.

Measurements of the discharge of siphon spillways show a discharge coefficient of about 0.6.

Automatic Gates—Details of a counterweight automatic gate developed by the Pacific Gas & Electric Company are shown on Fig. 23. The original installation of this gate did not prove entirely satisfactory owing to the excessive momentum acquired when opening or closing. The dashpot control was then added to limit the rate of motion and operation has since been satisfactory. The cost of this gate is very low. A small increase in head is sufficient to cause the gate to drop.

The Stickney automatic gate, which was used on the New York State Barge Canal, consists of two leaves connected rigidly and at right angles to each other and hinged at the point where they join. When the gate is down it rests in a recess in the crest of the dam. Operation is similar to that of the drum gate.

At Baldwinsville, N. Y., on the Barge Canal there is a modified type of Tainter gate which operates automatically due to the water pressure in the pond.

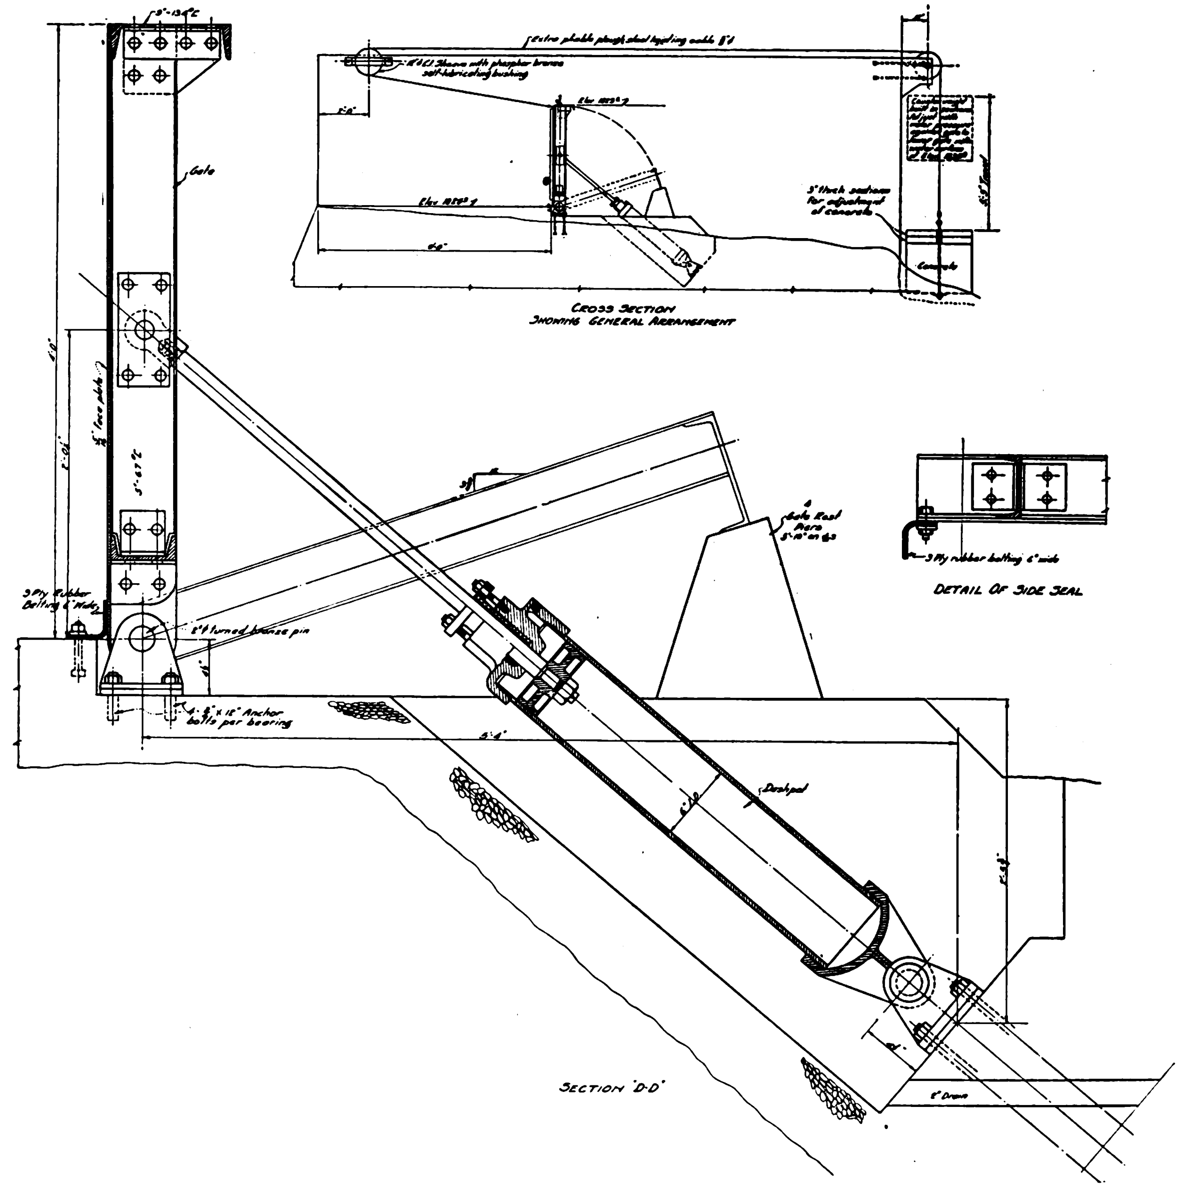

FIG. 23—ARRANGEMENT OF AUXILIARY AUTOMATIC FLOOD GATE, NEW YORK RESERVOIR.

Because of the lack of facilities for keeping the gate free from ice in winter, the automatic feature cannot be depended upon during this period of the year. In addition, back water on the downstream side of this gate interferes at times with its automatic operation (see Fig. 24).

Another type of automatic gate was installed at the Tallulah Falls development. It is pivoted at the bottom, and as it tilts, due to increased water pressure it causes a roller counterweight to move up an inclined plane. A similar type known as the Stauwerke gate uses a walking beam and counterweight. The degree of regulation of water surface for these two types is such that only several inches' rise will cause the gates to tilt. The gates return to their closed position when the water surface again becomes normal. The Stauwerke gates on the Wissota dam have been found to be lacking in sensitiveness, so that they sometimes open more than is necessary to take care of the increased flow, and therefore for a short time discharge considerably more water than is desired. In the same way they do not rise or close until after the head has dropped materially.

Automatic-control gates of California manufacture are being used widely. The gate is counterweighted and actuated by a float which may be governed by either the change in upstream or downstream water level.

The Pacific Gas & Electric Company has installed several of these gates, both for constant level upstream and for constant level downstream. These gates with one exception have operated successfully. The fault in the one case was in the setting of the pin bearing, which was easily remedied. Better results have been obtained with a rubber seal which crimps through an angle of 90 deg. and rubs on the

side walls rather than by providing a notch in the walls which permits the rubber belting to lie flat and parallel to the face of the gate.

GENERAL CONCLUSIONS

The conclusions drawn in a report of this character must necessarily be general. While the design and construction of spillways can and should be based on the fundamental principles of civil and mechanical engineering and hydraulics, the local influences of altitude, climate, topography, geological formation and other factors, must be carefully weighed in the selection of type of spillway gate, and in working out the details of design.

The size of spillway to provide is not strictly within the province of the report, but it would seem that the question of freeboard may properly be discussed. Freeboard should be defined and recognized as the amount of clearance beween maximum high water and the top of dam, or other structure under consideration. Properly speaking, the capacity of a spillway is limited by the permissible maximum depth of water on the crest. Any greater depth than this maximum is clearly an encroachment on the freeboard ostensibly provided, and a menace to the safety of the dam. Therefore, only in very special cases should the possible overtopping of gates be considered. If additional strength and ruggedness are desired, lower working stresses should be used, and the effect of impact provided for; but the desired strength should not be attained in the design by arbitrarily assuming a certain amount of overtopping. Before the problem of gates is attacked, the capacity of the spillway should be adequately determined and very definitely settled.

The question of economics will arise in connection with almost every spillway installation. The following factors should be given consideration:

(1) Value of gain in storage vs. cost of gates.
(2) Cost of flooding rights and clearing where higher reservoir surface will obtain with open type of spillway.
(3) Value of gain in storage due to the use of gates easily and quickly operated.
(4) Use of one type or size of gate on part of the crest suitable for ordinary regulation, and the use of another size or type for unusual flow conditions.
(5) Storage management with respect to the time and magnitude of peak floods.
(6) Investment cost and maintenance cost.
(7) Reliability of service and safety of operation.
(8) Relative costs of different types and locations of spillway on a given dam structure.
(9) The determination of the least total cost, which is the sum of the first cost plus the capitalized value of gain.
(10) Designs in anticipation of future changes and improvements, and designs of spillways for different stages of construction when dam is built in successive steps.
(11) The question of economy is again affected by policy and the question of conservatism. In general, government structures such as the Panama Canal are the most conservative of all, followed by government project structures of a semi-public nature, such as Reclamation Service projects. Public irrigation districts would be next on the list, followed by large, well-financed public utilities whose credit cannot afford to be impaired by the least possibility of failure of structures, and last in line smaller companies who cannot afford to spend any more in first cost than reasonably conservative engineering should require. These considerations must be borne in mind in reviewing the entire question of spillway gates and will not be the same for different companies.
(12) Insofar as policy and economy will permit, designs of spillways and spillway gates should conform as closely as possible with the structural and ornamental features of the main structure in order that the most pleasing and esthetic effect may be accomplished.

The materials of construction and stresses to be used for various types of spillway gates should not differ materially from those of other types of steel structures. The American Institute of Steel Construction specifications may well apply to gates made of structural steel. Gates of cast iron should not have tensional stresses greater than 2000 lb. per sq. in., nor compression greater than 12,000 lb. per sq. in. Cast steel stresses (Class B, Medium) should not exceed 14,000 lb. per sq. in. in either tension or compression; semi-steel when made with 25 per cent of scrap steel may have tensional stresses up to 3000 lb. per sq. in., and compression up to 12,000 lb. per sq. in. Steel forgings should permit stresses equal to those used for structural steel.

Bearing parts of most types of gates should be made of non-corrosive metal such as bronze or babbitt and be so designed that replacement may be made readily. Bronze screws for gate lifts have been recommended in some instances. The bearings of radial gate journals may be of steel if only the lifting effort is considered, as the leverage of lift is so great that a greatly increased friction in the journals will not increase the lifting load materially. The use of bronze bearings is to be recommended as an economical method of preventing undue wear at the bearings and consequent loss of true alignment of the gate.

The desirable speed of operation of most types of spillway gates varies over wide limits. Speeds greater than 2 or 3 ft. per minute are usually not necessary, and the greater speeds require relatively heavier operating mechanism. Where gates have rubber seals, faster speeds may result in excessive wear or possible binding. Norwegian practice has been based on a rate of opening of about 3 min. for the sector gates, 12 to 14 ft. high, and approximately 30 min. for the larger roller gates.

It is highly desirable to provide electric motor operation for spillway gates of any magnitude to reduce the time of operation. Some of the older types of hand-operated gates required hours to lift a single gate. The availability of electric power and expense necessary to bring electric power to remote localities has a great bearing on the problem. Remote or automatic control is desirable for gates of spillways of diversion dams to regulate the amount of water diverted into the conduit. Gates may be also supplemented by siphon spillways to advantage. Remote control of spillways of storage dams is not usually necessary.

The maintenance required for spillway gates is normally very inexpensive. Painting of gates in the original installation should be thoroughly investigated and some durable coating such as asphaltic enamels selected. The expense of maintenance painting then will be reduced to a nominal amount. The journals and operating mechanisms should be greased periodically and tested by partially raising and lowering the gates. This will insure that the gates are operative and break films of corrosion which may be forming.

The question of leakage and means to prevent it is important and has been discussed in connection with the several types of spillway gates.

MANUFACTURERS' STATEMENTS

STATEMENT BY THE ALLIS-CHALMERS MANUFACTURING COMPANY

Among a number of interesting installations during the year 1928 two are worthy of special attention in the brief space allotted to this report. The first of these is another world record impulse turbine put into operation on the Pacific Coast, and the second is a group of turbines establishing a record in Japan.

In March, 1928, the Bureau of Power and Light of the city of Los Angeles, Cal., awarded a contract to this company for an impulse wheel unit to complete the quota of turbines at their San Francisquito No. 1 Plant. This last unit is rated 32,200 h.p., maximum, under a net effective operating head of 800 ft., and is double the capacity of each of the four units previously installed at that plant. This unit does not beat the world record as to capacity held by the 56,000-h.p. impulse wheels described in last year's report as being built by this company for the Big Creek 2-A Plant of the Southern California Edison Company. Neither does it beat the company's previous world record as to operating head under which the 45,000-h.p., 2400-ft. unit built for the Balch Plant of the San Joaquin Light & Power Corporation, mentioned in the 1926 report. It does, however, beat the previous world record, described in an earlier report, held by the company's Caribou units, built for the Great Western Power Company and which in itself had 11-in. diameter jets and an impulse diameter of 155 in. The new San Francisquito No. 1 unit is also of the double overhung impulse type, but its two jets are each 14 in. in diameter with wheel diameters of 176 in. Fig. 1 shows a shop view of one of the two 52-in. cast steel nozzle pipes with needle, which produces one of the 14-in. jets just mentioned. The speed of 143 revolutions, designed for 50-cycle operation, is the lowest speed of any hydro-electric impulse wheel unit of large capacity. The generator, which also was designed and built by the company, is, therefore, one of the largest of its kind ever built. It is of interest to note that, although this is the largest impulse wheel unit, as to physical dimensions, ever built, it was put into operation before the close of the year in spite of the fact that the order was not placed until March of the same year.

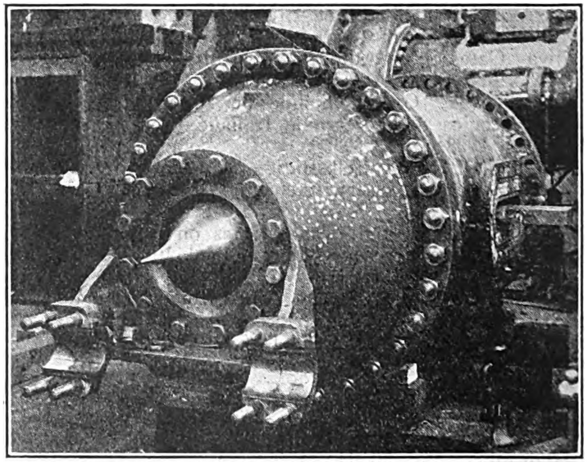

FIG. 1—NOZZLE PIPE AND NEEDLE FOR 32,000-H.P. ALLIS-CHALMERS IMPULSE TURBINE.

The year 1928 saw the complete manufacture and successful installation of three 36,000-h.p., single vertical plate steel spiral casing turbines built for the Saku Plant of the Kanto Suiryoku K. K. in Japan. These units established a record as to capacity of units previously installed in that country.

Fig. 2, in the foreground, shows the casing shop assembly of two of these units with their respective speed rings. These units operate under a normal net effective head of 390 ft., and, therefore, establish another world record in that they are the highest head plate steel spiral casing units ever built. The Allis-Chalmers patented plate steel spiral casings, which were used for this installation instead of the conventional cast steel casings, did much to eliminate

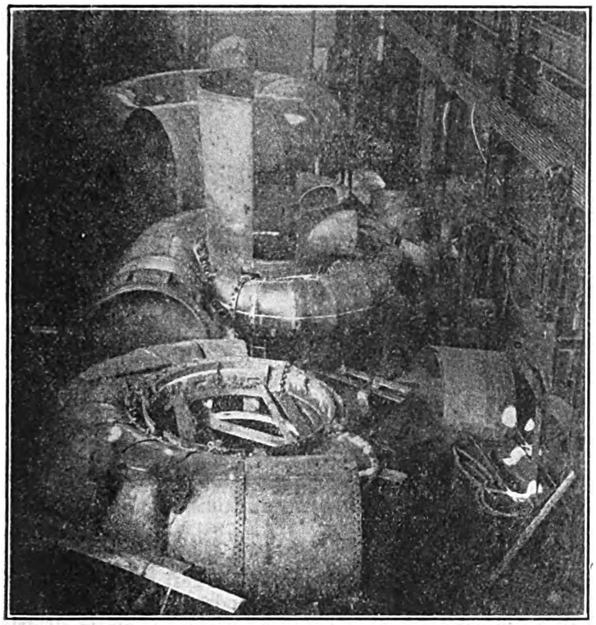

FIG. 2—PLATE STEEL SPIRAL CASING FOR 36,000-H.P. ALLIS-CHALMERS TURBINE.

transportation difficulties. Furthermore, in doing away with the handling of heavy cast steel casing parts with their difficult field assembly, the Allis-Chalmers plate steel spiral design did much to speed up the erection of these units, so that this plant went into operation ahead of the original estimated completion date. In addition to furnishing the three complete hydraulic turbines mentioned above, the company also furnished three 9-ft. diameter cast steel butterfly valves located at the spiral casing inlets, as well as three 11-ft. diameter cast steel butterfly valves placed at the upper ends of the respective turbine penstocks.

Fig. 3 shows two of these 11-ft. diameter butterfly valves in the foreground and one of the 9-ft. diameter butterfly valves in the background. All these are shown with their respective wickets, shafts and housings assembled together.

Among other installations of the past year, the six 5000-h.p. units built for the Chippewa Plant of the Northern States Power Company should be mentioned. These interesting units were designed for a normal operating head of 29.6 ft. and are of the high-speed propeller type, operating at 138½ r.p.m. In addition, the company has under design and construction—three 12,000-h.p., maximum, propeller type turbines for the Back River Development of the Montreal Island Power & Light Company. The runners, when built, will be 16 ft. in diameter for operation at a speed of 85 r.p.m. under a normal net effective head of 26 ft. When installed these units will establish a record on this continent as to physical dimensions.

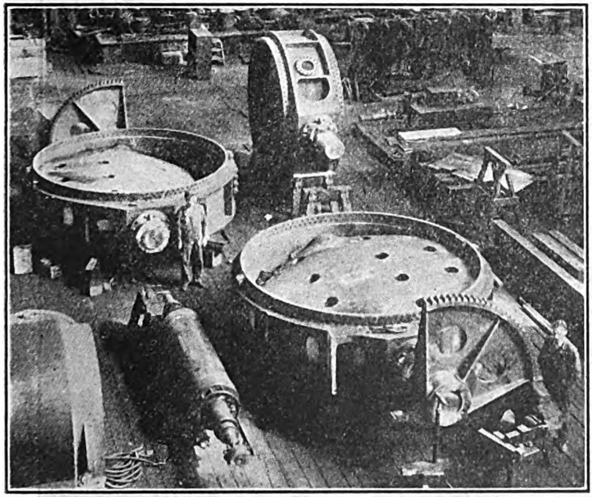

FIG. 3—SHOP ASSEMBLY OF THREE 11-FT. AND TWO 9-FT. ALLIS-CHALMERS BUTTERFLY VALVES.

Mention might also be made here of three 56,000-h.p. single vertical plate steel spiral casing turbines under construction, together with 16-ft. diameter butterfly valves, for the Calderwood development of the Knoxville Power Company. In the background of Fig. 2 also can be seen a 24,500-h.p. plate steel spiral casing turbine for operation under 112-ft. head, designed and built for the Bartlett's Ferry Development of the Columbus Electric & Power Company.

Space does not permit of mentioning numerous other smaller capacity units built or installed by the company during 1928.

STATEMENT BY JAMES LEFFEL & COMPANY

Although this company has been manufacturing water turbines since 1862, it has always specialized in what is termed "Low and Medium Head" field, not exceeding approximately 200 ft. head.

Also, although in 1920 this company erected and occupied an entirely new and thoroughly modern factory, with a view of equipping to build turbines of all sizes, it has always specialized in what are termed "Medium" and "Smaller" sizes.

Since there are four established, reputable manufacturers equipped for, and experienced in, the building of large turbines, this company has never felt it would be profitable to make the further investment in large tools necessary for building these large units, and thereby entering a new and highly competitive field. Its efforts, therefore, have been centered on the improvement of turbines within the field of head and sizes in which it specializes.

There has been considerable activity in recent months in the development of some extremely low heads, in comparatively high capacities. Some of these developments of special interest are the following:

West Missouri Power Company, Osceola Station: Two units, each operating under varying heads of 7 to 14 ft., at constant speed 120 r.p.m., each unit developing, under 14-ft. head, 1130 h.p.

These units are of high-speed type, designed with outside or exposed type gate operating mechanism. The penstocks are of decked, vacuum type, equipped with separate ejectors. The steady bearings are grease and water lubricated. The units are equipped with complete automatic remote control. These runners are approximately 112 in. in diameter.

Wisconsin Power & Light Co., Indian Ford Station: Two units operating at 90 r.p.m. Head varying from 4 to 6 ft. Capacity, each unit, at 6-ft. head, 281 h.p.

These units are of the submerged gate operating mechanism type, installed in decked, vacuum penstocks and equipped with complete, automatic remote control. These runners are approximately 102 in. in diameter.

Lake Superior District Power Company., Thornapple Plant: Two units operating at 120 r.p.m., under heads varying from 8 to 15 ft., each unit at 15-ft. head, developing 1170 h.p.

These turbines are installed in decked, vacuum type penstocks, with exposed type gate operating mechanism. The speed rings are cast solid. The turbine is fitted with automatic oil-lubricated steady bearings. These runners are approximately 112 in. in diameter.

City of Idaho Falls, Idaho: One unit, 21-ft. head, 1800 h.p., 150 r.p.m.

This unit is installed in a decked concrete penstock. The turbine has solid speed ring and exposed type gate operating mechanism, and self-lubricating oil steady bearing.

A very interesting development, which is in the nature of an experiment, is now being made by the Lowhead Water

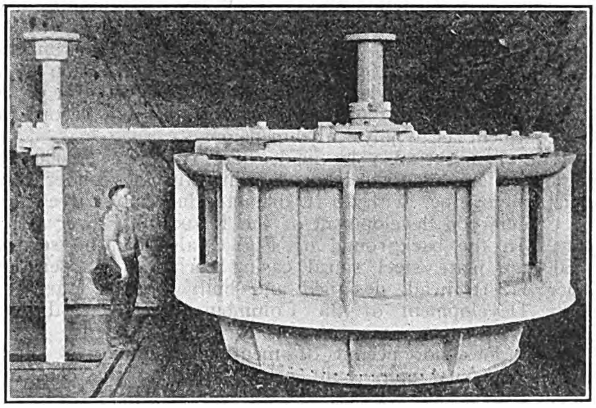

FIG. 4—LEFFEL TURBINE WITH SUBMERGED TYPE GATE MECHANISM AND ADJUSTABLE LIGNUM VITÆ BEARING.

Power Company, Beaufort, S. C., where they are installing one unit, 7-ft. head, 100 h.p., 164 r.p.m. This unit is operated by the rise and fall of the tide. There are a number of unique and interesting features in connection with it. If it proves entirely satisfactory, additional tide-water developments will be made.

Fig. 4 and 5 illustrate a typical vertical, direct-connected type of turbine with submerged type of gate operating mechanism, using lignum-vitæ steady bearing designed for adjustment in four directions.

Fig. 6 and 7 illustrate types of exposed or outside type of gate operating mechanism. The steady bearing shown on Fig. 7 uses six heavy, solid, lignum-vitæ bearing blocks, while in that shown in Fig. 6 self-lubricating oil steady bearings are used.

Almost all of these medium and low head plants are now equipped with complete remote control.

STATEMENT BY I. P. MORRIS & DE LA VERGNE, INC.

In March, 1928, several months ahead of schedule, the 54,000-h.p. Conowingo turbines were placed in successful commercial operation. From the start these turbines, which are outstanding in that they are the largest in overall physical dimensions of any turbines yet undertaken, have operated with an absence of any major difficulties. This is gratifying in view of the unprecedented size of the parts involved. The 27-ft. butterfly valves with rubber tube sealing devices have been most successful in saving water during the shutdown period of the turbines. These units now form a very important element in the generating capacity of the Philadelphia Electric Company's system. During low flow periods they are operated at peak load and during high flow periods continuously on base load.

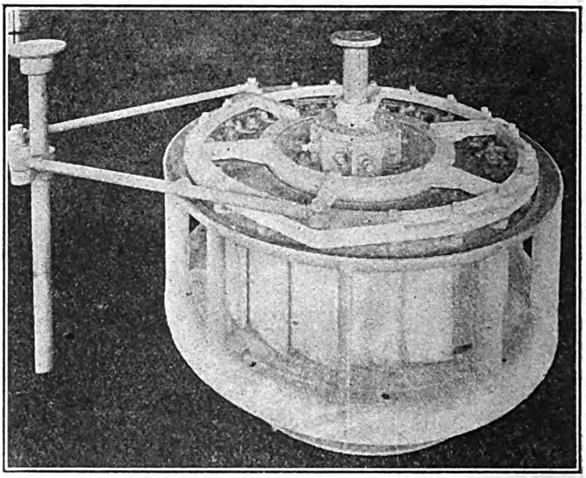

FIG. 5—LEFFEL TURBINE WITH SUBMERGED TYPE GATE MECHANISM AND ADJUSTABLE LIGNUM VITÆ BEARING.

Hydro-electric development in Canada continues at a very rapid pace, owing to the comparative absence of steam competition and to the large number of undeveloped water power sites: The principal contracts obtained by this company and by our licensees, the Dominion Engineering Works, Ltd., during the year 1928, are as follows:

One 43,000-h.p. turbine for the Shawinigan Engineering Company, for installation at Shawinigan Falls, Quebec. Head, 145 ft.

Two 31,000-h.p. turbines for the Great Falls Power

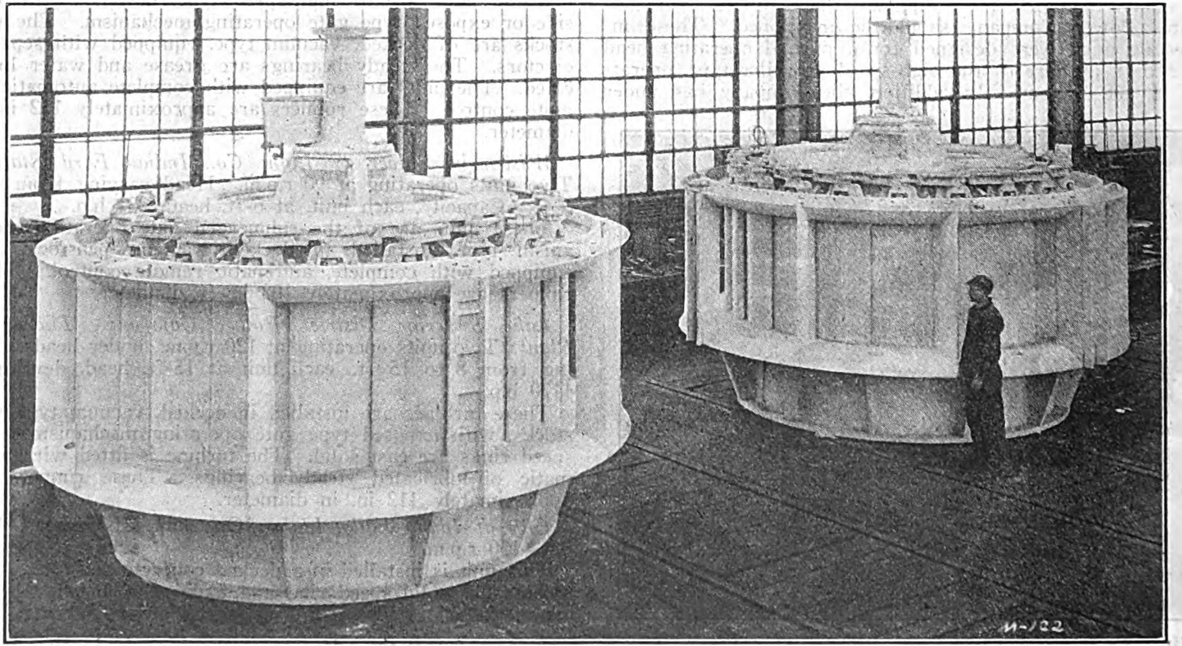

FIG. 6—LEFFEL TURBINE WITH OUTSIDE TYPE GATE MECHANISM AND SELF-LUBRICATING OIL STEADY BEARING.

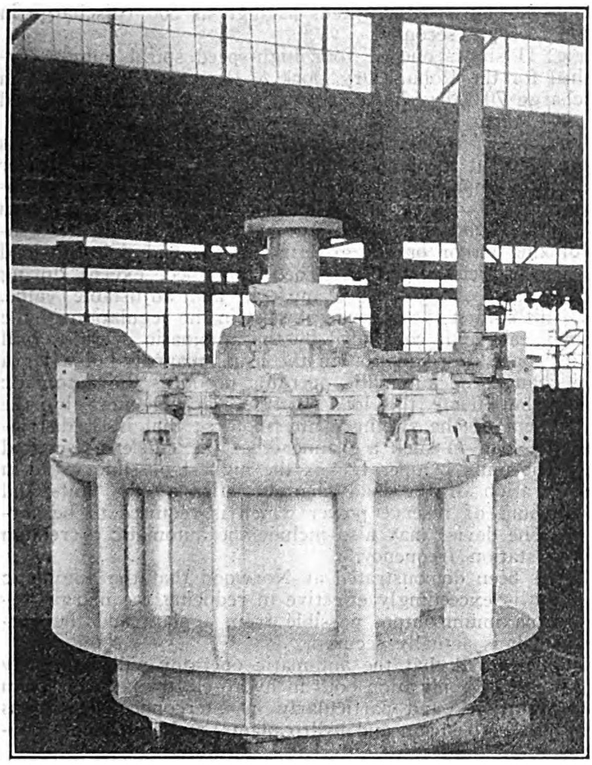

FIG. 7—LEFFEL TURBINE WITH OUTSIDE TYPE GATE MECHANISM AND LIGNUM VITÆ STEADY BEARING.

Company, Montana, Morony Development. Head, 82.5 ft.

Two 36,000-h.p. turbines for the Alabama Power Company, Lower Tallassee Development. Head, 88 ft.

Two 19,200-h.p. turbines and one 8550-h.p. turbine for the Turners Falls Power & Electric Company, Cobble Mountain Development. Head, 420 ft.

Two 18,000-h.p. turbines for Calgary Power Company, Ghost River Development. Head, 105 ft.

Two 12,000-h.p. turbines for the Corporation of the City of Winnipeg, Slave Falls Development. Head, 30 ft. Propeller type units.

One 15,700-h.p. turbine for St. Lawrence Valley Power Corporation, Colton Development. Head, 270 ft.

Three 14,000-h.p. turbines for Churchill River Power Company, Flin Flon Development. Head, 56 ft. Propeller type units.

Two 3000-h.p. turbines for Nova Scotia Power Commission, Upper Hooke Falls Development. Head, 31.5 ft. Propeller type units.

The aggregate capacity of propeller type units constructed by this company and the Dominion Engineering Works, Ltd., up to the end of 1928 totals 485,000 h.p.

The Morony turbines are duplicates of the 25,600-h.p. turbine which this company furnished for the Norwood Development of the Carolina Power & Light Company. In line with modern practice, the Cobble Mountain turbines will not be provided with relief valves, but are designed to take care of the pressure rise resulting when the governors close the gates at the maximum rate possible. This maximum rate will be fixed by non-removable diaphragms located in the governor piping.

The Alabama Power Company's Lower Tallassee turbines are equipped with rubber sealing strips set into the face of the upper and lower distributor plates in such a manner that when the movable guide vanes close these vanes are in contact with the strips. This reduces very effectively the amount of leakage through the turbine gates in the closed position, and this feature is coming to be of increasing importance in conjunction with the peak operation of turbines, which often necessitates the turbines being shut down with pressure in the casings during an extended period each day.

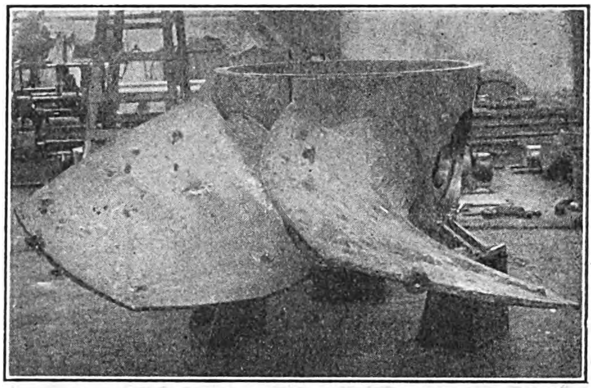

FIG. 8—I. P. MORRIS 8800-H.P. PROPELLER TYPE RUNNER.

The construction by the Dominion Engineering Works, Ltd., of the 8800-h.p. propeller type units for the Back River Development of the Montreal Island Power Company, Ltd., is of interest. The vanes of these runners will be manually adjustable. Fig. 8 and 9 show, respectively, the photograph of the runner during the assembly with the blades in the shops and a sectionalized aluminum model, showing the operating mechanism. In this mechanism the turbine of the runner vanes is accomplished by means of a lubricated sliding shoe without the use of gearing at this point, thus reducing materially the bearing pressure, lost motion and wear, which accompany the use of gears. These runners will have a diameter of about 15½ ft., and with the exception of the Lila-Edet turbines in Sweden, are believed to be the largest, in point of dimensions, of any adjustable blade propeller runners yet undertaken, and the largest in capacity, including the Lila-Edet units.

Fig. 10 represents a view of our new hydraulic laboratory for testing model turbine runners and pumps. The design is such that the same weir is used for the measurement of the water when a pump is being tested as when a turbine is being tested, this weir having been calibrated volumetrically.

A unique feature in connection with the laboratory is the

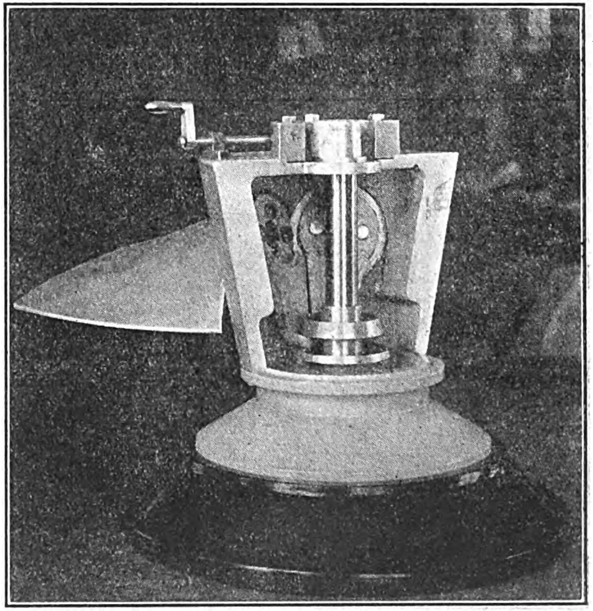

FIG. 9—SECTIONALIZED ALUMINUM MODEL OF RUNNER SHOWN IN FIG. 8.

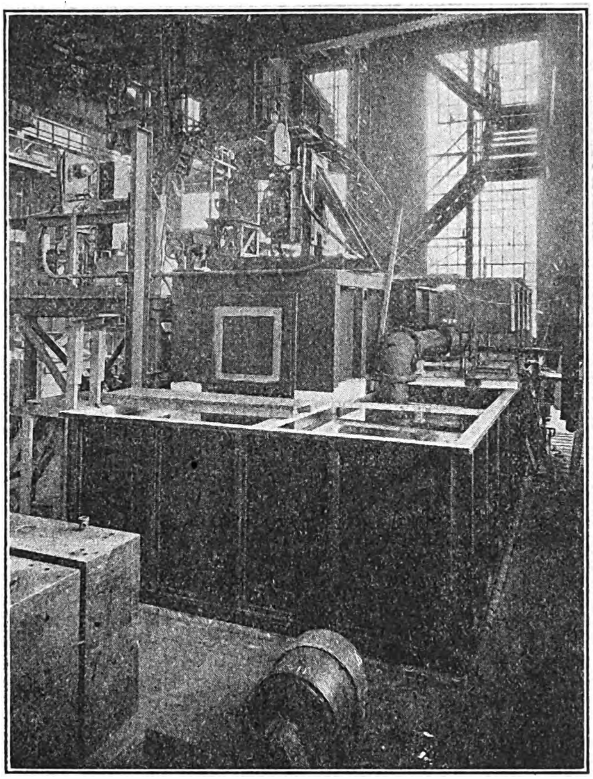

FIG. 10—HYDRAULIC TURBINE AND PUMP TESTING LABORATORY OF I. P. MORRIS & DE LA VERGNE, INC.

use of an electric dynamometer, which permits the accurate measurement of the power developed by the turbine and of the power required to drive the pump under test. As the stationary element of the dynamometer is mounted so that the torque being developed is measured by weighing scales, the efficiency of the dynamometer when operating as a motor or as a generator does not enter into the calculations. A very satisfactory control of speeds is possible.

The Moody spiral pump, which represents an application of the propeller type of runner for pumping, is experiencing broader application where the amount of water to be pumped is large and the head not higher than 40 to 50 ft. These conditions make high specific speed desirable, and these pumps develop specific speeds as high as 500 (discharge in cubic feet per second).

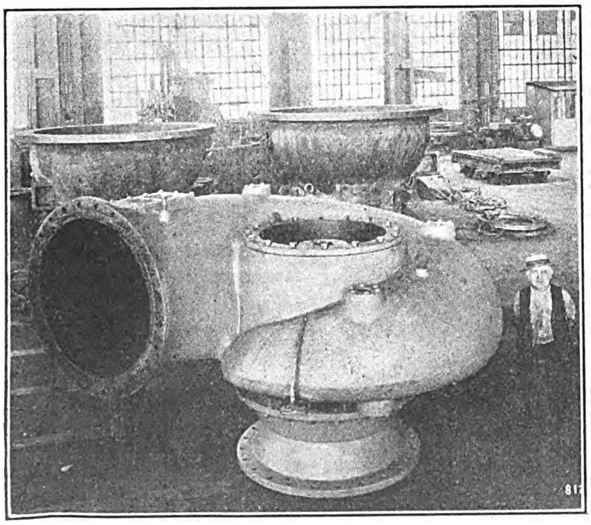

FIG. 11—HIGH SPEED SPIRAL PUMP, 70,000 G.P.M., 26-FT. HEAD, I. P. MORRIS & DE LA VERGNE, INC.

Fig. 11 shows one of four high-speed spiral pumps furnished for the Robins Dry Dock & Repair Company, which discharge 70,000 g.p.m. against a head of 26 ft. at a speed of 400 r.p.m.

The first installation of an automatic operator has taken place at the Norwood Station of the Carolina Power & Light Company and is now in successful commercial operation. This instrument has been devised for installation on the switchboard for the automatic operation of the synchronizing motor on the governor to the end that the load on any particular unit may be maintained, except during sudden load changes, at a uniform and adjustable value.

If this station is required to assist in the regulation of the system, each unit controlled by the automatic operator will do its share of regulation in the usual manner, but after a load change the automatic operator produces the automatic re-distribution of the load on the various units by the adjustment of the synchronizing motors; that is, it distributes the load in such a manner that the efficiency secured from the units in operation is the highest possible value in consideration of the load characteristics of the units and the amount of reserve power which is required to be carried. The device may also include the automatic correction of the station frequency.

It has been demonstrated at Norwood that the automatic operator is exceedingly effective in reducing the margin between maximum output possible from a plant and the output which is actually secured.

It is believed that the automatic operator will ultimately have a broad application both in hydro-electric and in steam power stations, and particularly in interconnected stations involving both steam and hydro plants, and in systems having stations subject to different conditions.

STATEMENT BY THE NEWPORT NEWS SHIPBUILDING & DRY DOCK COMPANY

Turbines

The following units are among those completed by this company and put into commercial operation during the past year:

(a) One 12,000-h.p., 75-ft. head, 133.3-r.p.m. vertical turbine for the Clarion River Power Company, Piney Station. This unit is of interest in that the built-in parts were already installed and were only designed for an 11,000-h.p. turbine whereas the unit gave an output of more than 12,500 h.p. on field test.

(b) Two 28,000-h.p., 90-ft. head, 120-r.p.m. vertical turbines for the Western Carolina Power Company, Oxford Station. These units have the Newport News type elbow draft tube (patented) described and illustrated in this company's last statement. These tubes have been found to function very satisfactorily and efficiently without vibration at any load condition and with a very satisfactory discharge appearance.

(c) One 10,000-h.p., 439-ft. head, 450-r.p.m. vertical turbine for the Braden Copper Company, Coya Station, Chile, S. A.

(d) One 3400-h.p., 65-ft. head, 240-r.p.m. vertical turbine for the U. S. Bureau of Reclamation, Gremsey Plant.

Two of the above installations have the Newport News type oil bearings (patented), illustrated in Fig. 12. This type of bearing was described in the last report and provides a positive separation of the oil in the sump below the bearing and any water leaking up around the shaft through the stuffing box, at the same time providing ready access for adjusting the packing gland while the unit is in operation, or renewing the packing without dismantling any portion of the bearing.

Two 4800-h.p., 32-ft. head, 150-r.p.m. and one 3400-h.p., 32-ft. head, 180-r.p.m. units, which were built during the past year for the West Florida Power Company, Jackson's

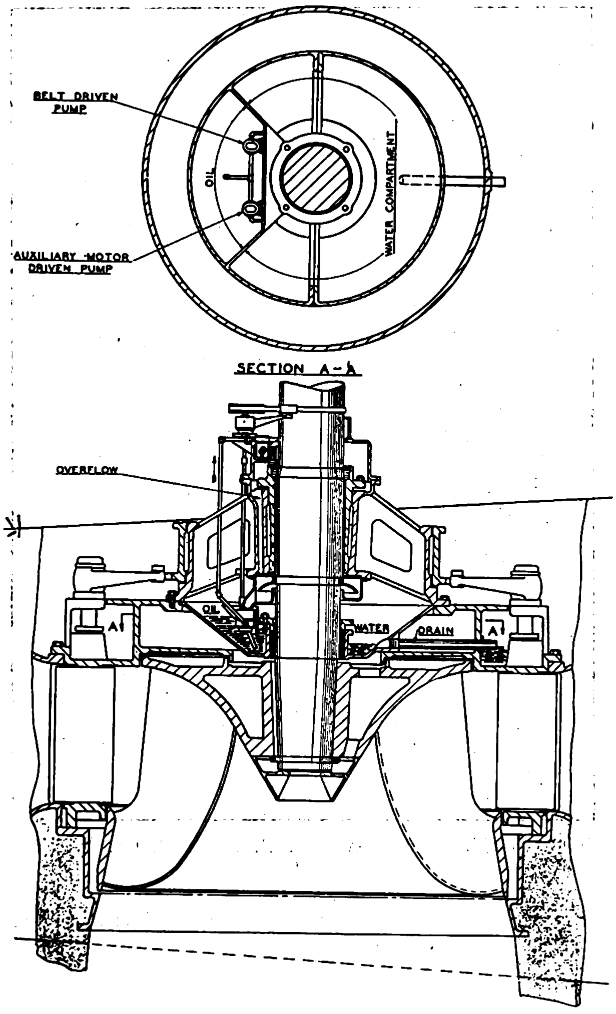

FIG. 12—PATENTED OIL BEARING, NEWPORT NEWS, S. B. & D. D. CO.

Bluff Station, are now being erected, and have runners of the propeller type. A 40-in. model of these runners showed a record performance of 92.2 per cent maximum efficiency on Holyoke Test and gave over 90 per cent efficiency over a range of specific speed from 115 to 180, which makes this type especially suitable for plants with large variations in head.

New contracts received during the past year include the following:

	No. Units	H.p. per Unit	Head in ft.	R.p.m.
Hydro-electric Power Commission of Crisp County, Ga.	1	6,000	30	100
Hydro-electric Power Commission of Crisp County, Ga.	1	3,600	30	100
City of Cookeville, Tenn.	1	1,600	230	720
South American Gold & Platinum Company	1	1,200	13	72

The units for Crisp County, Georgia, are of special interest in that the engineer selected a combination of Francis and propeller type runners of different capacities, so that an extremely high efficiency would be obtained throughout the power range of the plant.

The principal parts for the unit for South American Gold & Platinum Company were split up sufficiently so that no part would weigh over 6000 lb., in order to facilitate transportation to the power house.

A distinctly forward step was taken in runner construction in the successful building of a completely welded double runner to develop 15,000 h.p. under 250-ft. head at 360 r.p.m. This runner, shown in Fig. 13, was built for the Tennessee Electric Power Company to replace a cast-iron runner whose life had proved short on account of the unusually severe operating conditions. Separate steel castings were made for the hub and bands, and the water passage surfaces machined to the correct dimensions. The 19 vanes were pressed by dies from ⅝-in. boiler flange steel, one double vane being formed as a unit. The vanes were trimmed to templet and tack welded to the hub, then the bands put in place and tack welded, after which the vanes were completely welded to the hub and bands. The runner was annealed without scaling and finally finished the same as a solid cast runner. The resulting runner proved to be unusually strong, rigid and smooth.

Castings for double runners are very difficult in iron, besides not being susceptible to ready repair by welding when pitted or eroded, and are practically out of the question in solid cast steel. This partly accounts for manufacturers discontinuing the building of double runner units. It is possible that the use of welded runners will open up a new field in the use of double runners for relatively high heads. Double runners possess the advantage of being practically hydraulically balanced axially; they have less rotating surface in contact with water, which reduces the skin friction loss to a minimum; there is no leakage loss around the hub of the runner such as in the case with single runners; a higher rotating speed gives reduced generator cost, and the resulting turbine is somewhat less expensive than the equivalent single runner turbine. Obviously, it is only applicable to horizontal machines, but, as there seems to be some tendency toward a return to horizontal machines for relatively high heads, this does not appear to be a disadvantage.

Mechanical Rack Rakes.

Thirteen installations were contracted for during 1928, bringing the total number of installations to sixty-one and involving the use of ninety-eight rakes.

This type of rack rake has become so standardized, so simple in its construction and operation, and its economy so well known that very little new of interest can be said about it. However, a somewhat special installation is shown in Fig. 14. This installation was made at the York Haven Station on the Susquehanna River. The space for the

Turbines

The problem of developing hydro power in the West is generally co-existant, to a minor or major degree, with that of irrigation and domestic water supply. Two developments where this situation existed to a major degree were prosecuted during 1928. The Coolidge Dam and reservoir just completed, on the Gila River in Arizona, by the U. S. Indian Irrigation Service is primarily for irrigation service, and provides a storage of approximately 1,200,000 acre ft. The power to be developed, however, renders this undertaking economically satisfactory and this company have under construction in its San Francisco Works, two vertical Pelton, reaction turbines complete with governors, oil pressure sets and accessory hydraulic equipment for the Coolidge Dam power house. Each unit will develop 9200 h.p. under 220-ft. effective head at 300 r.p.m. The design is such as to provide maximum efficiencies under variable head, the range being from 140 ft. to 220 ft.

The East Bay Municipal Utility District is completing its main storage reservoir on the Mokelumne River at Pardee Dam, where 20,000 h.p. will be developed as a by-product of the domestic water supply for the cities on the eastern shore of San Francisco Bay. The power house will include two 10,000-h.p. vertical Pelton reaction turbines, operating under a normal effective head of 300 ft.—the range of head being 125 ft. These turbines will be complete with Pelton governors, oil pressure sets and accessory equipment.

Among the notable Pelton installations in 1928, in the reaction turbine field, the No. 2 Unit of the Big Creek No. 8 Plant of the Southern California Edison Company, illustrated in Fig. 16, may be mentioned. The shop assembly, as illustrated, was subjected to a hydrostatic test of 700 lb. per sq. in. which was maintained continuously for 24 hr. while the stresses and strains at critical points were checked at intervals with a strain gage which indicated them to be well within design limits. This turbine has a rating of 44,000 h.p. under a static head of 715 ft. at 375 r.p.m.—a record capacity in the West for a unit operating under such a high head.

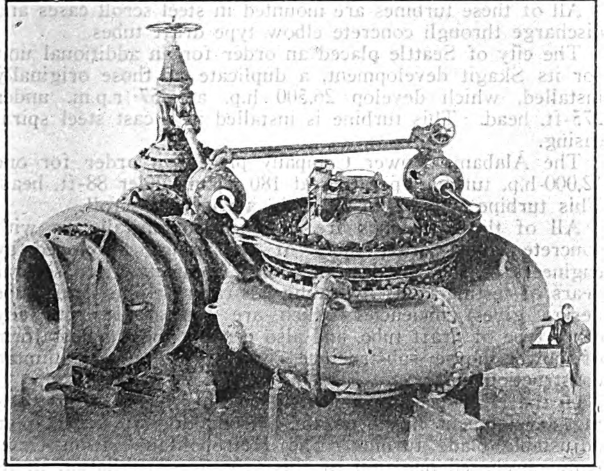

FIG. 16—44,000-H.P. PELTON TURBINE, 715-FT. HEAD.

Important progress has been made in the field of automatic hydro plants, an outstanding example being the Spaulding No. 3 Unit of the Pacific Gas & Electric Company. Here all of the principal operating functions of the turbine and auxiliaries are performed hydraulically, using the water pressure direct from the penstock, with electrical control. A novel improvement is the hydraulic controller which replaces the oil pressure governor and which performs all of the functions of starting, loading and shutdown, for block load plants, without requiring any oil pressure system and its attendant complications. A complete description of the automatic features of this plant has been published in the May 15, 1928, issue of *Electrical West* in a report of the Hydraulic Power Committee, P. C. E. A., and will again appear in the serial report of the Hydraulic Power Committee, N. E. L. A., in due course.

The successful operation of automatic hydro-electric plants has conclusively demonstrated their reliability and economic advantages over manual control, with a result that many existing equipments are being converted to automatic operation. Since the principles of operation are practically independent of the size of equipment, there is no doubt that automatic control and operation will be applied to large capacity equipment in the future.

Impulse Wheels

Among the notable Pelton impulse installations placed in service during the year 1928 may be mentioned the Big Creek 2-A Unit of the Southern California Edison Company, shown in Fig. 17. This is a characteristic double overhung, single nozzle assembly with governor operated, straightflow power nozzles with individual auxiliary relief needle pressure regulating nozzles. Shortly after being placed in service, this unit was called upon for outputs of 70,000 h.p. and over, which it carried continuously in a very satisfactory manner; a record performance with impulse equipment.

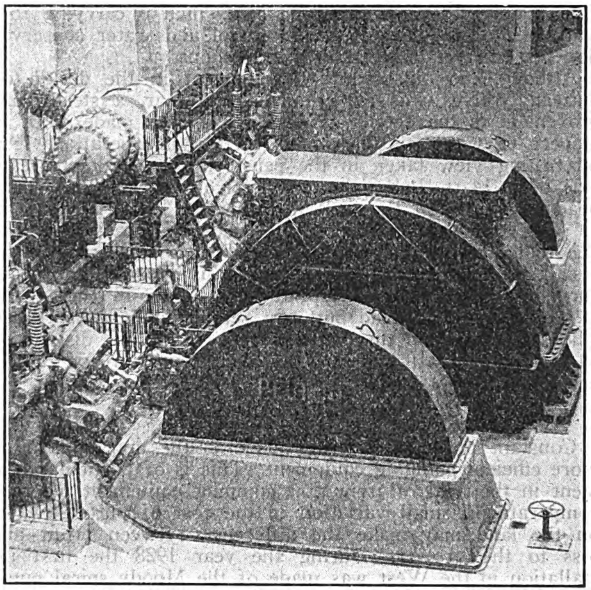

FIG. 17—70,000-H.P. PELTON DOUBLE OVERHUNG IMPULSE WHEEL.

The Bucks Creek Plant of the Feather River Power Company, illustrated in Fig. 18, containing two horizontal,

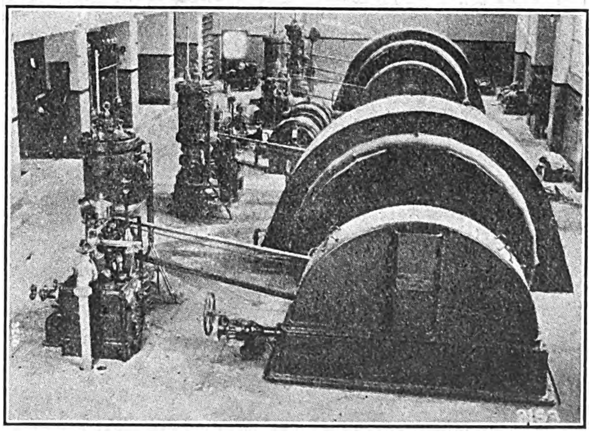

FIG. 18—35,000-H.P. PELTON DOUBLE OVERHUNG IMPULSE WHEEL, 2562-FT. HEAD.

double overhung, single nozzle units each furnishing 35,000 h.p. at 450 r.p.m., was placed in successful service under a record static head of 2562 ft. The acceptance test for efficiency of the hydraulic equipment, with water quantity measured by the Allen salt velocity method, disclosed a maximum efficiency of 85.5 per cent at the normal operating point with efficiencies in excess of 85 per cent over a wide range of load.

Valves

The use of Larner Johnson free discharge valves for water flow regulation in storage dams for irrigation and water supply service is being constantly extended. The size and height of such dams has been increased to a remarkable extent during the past few years, and the higher heads thus produced necessitate the use of this type of valve for discharge regulation. A number of these valves were installed during 1928, several being furnished to the Los Angeles Flood Control District which is carrying forward one of the largest flood control and water conservation projects yet undertaken in this country.

Although no outstanding development in the design of butterfly valves was made during the year, a steady improvement in the details of design has been made, both in respect to water tightness and facility in operation. An interesting view taken in the penstock on the downstream side of a 14-ft. Pelton butterfly valve with the full static head of 45 ft. on the disk is shown in Fig. 19. As can be seen from the illustration, the leakage is practically zero due to the adjustable, sectionalized bronze seat ring on the disk. Another interesting valve of this type is that being furnished for the 44,000-h.p. turbine shown in Fig. 1. It is the largest high head butterfly yet installed in the West. The static head on this valve is 720 ft. and the disk is of 84 in. diameter. It was shop tested at a pressure of 725 lb. per sq. in.

Pumping Equipment

Constant progress is being made in the development of more efficient pumping equipment. This is of particular moment in the field of irrigation pumping equipment where a comparatively small variation in the cost of putting water on the land may make the difference between profit and loss to the grower. During the year 1928 the first installation in the West was made of the Moody spiral pump —a high-speed, low-lift pump of high efficiency manufactured by this company at the San Francisco Works. Seventeen of these pumps, each of 20,000 g.p.m. capacity, are being installed by the West Stanislaus Irrigation District in Central California.

Another notable installation of this type of pumping equipment is being made by the Patterson Water Co. at Patterson, Cal., to whom this company is furnishing 25 of these units to replace obsolete pumping equipment. The economic analysis as made by the engineers of the water company indicates that a saving of $17,000 per year in operating costs will be effected.

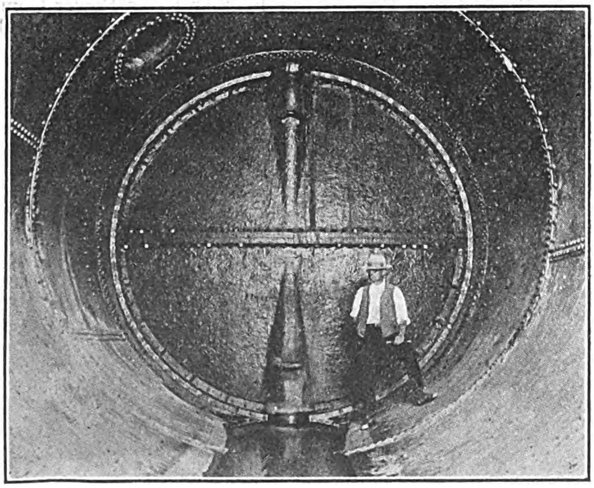

FIG. 19—14-FT. PELTON BUTTERFLY VALVE.

STATEMENT BY S. MORGAN SMITH CO.

During 1928, a year marked by many important activities in the field of hydraulic power development, this company was awarded a number of large contracts for turbines, some of which involved features of much importance. The total power involved in these contracts, including the orders placed with the company's Canadian associates, the S. Morgan Smith-Inglis Company, amounts to more than 1,000,000 h.p.

The largest turbines ordered during this period were four vertical shaft units set in 17-ft. diameter steel spiral casings for the Alcoa Power Company at its Chute-a-Caron development. These turbines, the runners of which are made of cast steel, are designed to develop 75,600 h.p. each, at 120 r.p.m. under 165-ft. head. This company also was awarded the contract for four units for the Saluda development of the Lexington Water Power Company in South Carolina. These units will each develop 55,650 h.p. under 180-ft. head, operating at a speed of 138½ r.p.m. Four units of the same size and type also are being built for the Lower Fifteen Mile Falls development of the New England Power Construction Company. These units will be rated at 53,100 h.p. at 138½ r.p.m. under 175-ft. head. The Brazilian Hydro-Electric Company awarded this company the order for the third unit for its Parahyba plant, this unit being designed to develop 40,000 h.p. at 125 r.p.m. under a head of 104 ft. The James Maclaren Paper Company of Buckingham, P. Q., has ordered three 30,000-h.p. vertical units operating at 180 r.p.m. under 180-ft. head.

All of these turbines are mounted in steel scroll cases and discharge through concrete elbow type draft tubes.

The city of Seattle placed an order for an additional unit for its Skagit development, a duplicate of those originally installed, which develop 26,500 h.p. at 257 r.p.m. under 275-ft. head. This turbine is installed in a cast steel spiral casing.

The Alabama Power Company placed an order for one 12,000-h.p. turbine operating at 180 r.p.m. under 88-ft. head. This turbine will be installed in a concrete scroll.

All of these turbines are designed for installation with concrete elbow draft tubes of the design developed by engineers of the S. Morgan Smith Company after several years of testing in its hydraulic laboratory. This draft tube design gives efficiencies which are comparable with any other type of draft tube, and also permits the simplest form of power house substructure, which results in minimum construction costs.

In the high-speed turbine field possibly the most interesting development has been the introduction of the Kaplan adjustable blade turbine. The Metropolitan Edison Company purchased one unit of this type for installation in its York Haven plant. This unit has manually adjustable runner vanes. The turbine is installed in an old flume which is very greatly restricted, and which necessitated special design for conducting the water to the runner. The draft tube is of the concrete elbow type. This unit is rated at 2750 h.p. under 26-ft. head at 200 r.p.m. It has been in satisfactory operation for some time, but as yet efficiency tests have not been completed.

The first automatically controlled adjustable blade Kaplan turbine was ordered by the Central Power & Light Company for its Devils River No. 9 development in Texas. This unit (Fig. 20) is of the 4-blade type with the blades automatically controlled by an oil pressure governor. The unit is rated at 1900 h.p. under 33-ft. head at 300 r.p.m. Due to the very flat efficiency curve of the Kaplan turbine, and also to its ability to take overloads of up to 20 per cent beyond the point of best efficiency with only a very slight loss in efficiency, it is expected that the yearly output will be greatly increased. During the past year orders for three similar automatically adjustable blade units were received from the Nova Scotia Power Commission for its Tusket Falls development, these units being rated at 1052 h.p. at 225 r.p.m. under 27-ft. head, and from the Wisconsin Power & Light Company for one unit for its

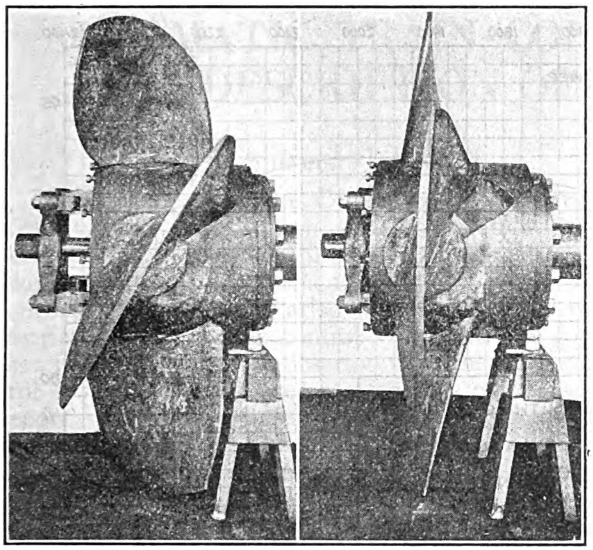

FIG. 20—AUTOMATICALLY ADJUSTABLE BLADE, KAPLAN RUNNER, S. MORGAN SMITH CO.

Rockton development, which will develop 750 h.p. at 100 r.p.m. under 10½-ft. head. The two illustrations show the Kaplan automatically adjustable blade runner with the blades in the fully opened and fully closed positions.

During the year efficiency tests were conducted at a number of plants, and some of these results are shown by the accompanying curves. The test curve for the Santeetlah development of the Tallassee Power Company (Fig. 21) shows the results of a high head type unit. This turbine was designed to operate over a range from 500 to 660-ft. head, with the point of best efficiency at about 560 ft. Conditions were such that the test had to be run with a head of 660 ft., and it is expected that at 560 ft. 1½ per cent higher efficiency could be obtained at the best point. The draft tube used with this turbine was of a special type designed by the Hydraulic Engineer of the Aluminum Company. An interesting test of a small capacity unit is that of the station service unit built for the Conowingo plant of the Philadelphia Electric Company. This turbine was tested by both the Allen salt velocity and by the Gibson methods, which differed only 0.3 of 1 per cent in efficiency at the peak. The test for the Alabama Power Company's Jordan Dam development was made by the Allen salt velocity method, and the results are as shown on the curve illustrated by Fig. 23.

In addition to the turbines described above, a great many units of various sizes were built both in the Francis and high-speed Kaplan types.

The Dow disk-arm butterfly valve continues to be popular, and orders were received for a number of these valves in very large sizes.

Interest has continued in the company's hydraulic testing laboratory, and a number of power companies have conducted tests there covering new and reconstruction work in order to determine definitely what results will be obtained under conditions and structures that otherwise would leave considerable room for doubt as to the ultimate results.

AUTOMATIC TRAIN CONTROL INSTALLATIONS AND DESCRIPTION OF THE CODE SYSTEM*

Summary

The first report of the Committee on Automatic Train Control, dated March, 1927, called attention to the fact that problems of inductive coordination between train control systems and adjacent power and lighting circuits might arise particularly in urban districts when the train control system utilized commercial frequencies. A description of the train control systems then in use was made a part of the report. Since the publication of this report the installations of train control systems called for under the first and second orders of the I. C. C.* have been completed. In addition, several railroad systems have extended their control installations beyond that demanded by the orders of the Commission.

There has also been a pronounced trend toward the utilization of those systems of train control that are inherently either immune or less susceptible to interference from adjacent power line installations. This movement has been seen in the development of new apparatus and the utilization of frequencies of the order of 100 cycles for the operation of the train control system. In some cases power at this frequency is also used for the operation of the wayside signals. This obviates the necessity of one distribution system for the supply of energy to these signals and another for the train control system. Also, train control apparatus has, by changes in design, been made less susceptible to interference from adjacent power systems. This has been made possible by better design and arrangement of the pickup coils and bar mounted on the locomotive and by a more sharply tuned circuit in the amplifying equipment between the pickup coils and the relays which actuate the signals in the locomotive cab.

The I. C. C. has recently announced that "Without minimizing the need for automatic train control it is more imperative that grade crossings be abolished." It is probable, therefore, that no new mandatory orders, calling for additional train control installations, will be issued but that instead the Commission will depend upon the carriers to amplify and extend their present systems of train control as they may deem most advisable. This marks a change in the attitude of the Commission regarding train control.

In order to summarize the present status of train control installations, together with a description of the code system which has been introduced since the publication of the first serial report of this subcommittee, the following report has been prepared. It summarizes the installations made following the first and second orders of the I. C. C. and also those installations made voluntarily. The report includes a description of the new code system of continuous inductive train control as developed by the U. S. & S. Co. The report also includes a discussion of the present aspect of the inductive coordination problem between the railway utilizing train control systems and the electric light and power companies. In conclusion, a very condensed digest of the hearings this year on the subject before the I. C. C. is given.

The greater part of the work of preparation of the material in this resumé, as well as the description of the new code system, has been done by Frank F. Fowle. The Subcommittee on Automatic Train Control wishes to acknowledge at this time the very great assistance of Mr. Fowle in the preparation of this report.

Status of Train Control

Summary of Installations

The statistics on train control installations as of March, 1928, are summarized in the nine attached tables, which are next explained. The I. C. C. has issued no further general orders calling for installations or extensions, since the so-called second order, but there are several railroads which have made voluntary installations in addition to those ordered by the I. C. C. The installations under the first two orders are now practically complete, as of July, 1928, but voluntary installations are still in progress, and very probably this class will increase as time goes on.

Grand Summary

Table I shows the grand summary of installations as of March, 1928, for which details are available. This table shows the 49 roads cited in the I. C. C. orders, of which five are exempted, leaving 44 required to comply. The table shows the installations under the first order and the second order, those made voluntarily, and the grand total which embraces 19,765 miles of track and 8142 locomotives.

TABLE I(A)

	Road Miles	Track Miles	Number of Locomotives
First Order	4,313.94	7,620.70	4,581
Second Order	4,073.12	7,532.60	2,802
Voluntary	3,444.09	6,425.14	759
Total	11,831.15	21,578.44	8,142

Average miles of road equipped per locomotive equipped: 1.4
Average miles of track equipped per locomotive equipped: 2.6

Table I(A) shows the total reported mileage, including certain voluntary installations for which details are not available. This table shows totals of 11,831 road miles, 21,578 track miles and 8142 locomotives. These figures are understood to be complete except for 284 locomotives of tenant roads operating over some of the installations shown in Table I.

Groups by Mileage

Under the I. C. C. orders it was generally the case that any given installation covered one engine division. It is interesting to observe the range of aggregate mileage of different railroad systems and this has been developed in Table II, where the first column shows the mileage on individual railroads comprising the system, and the installations by entire systems have been divided into those of 1000 total track miles or less and those of more than 1000 miles. This shows that there are 11 individual railroads which form parts of complete systems having aggregate track mileage of installations exceeding 1000 miles per system.

TABLE II

SUMMARY OF INSTALLATIONS GROUPED ACCORDING TO TOTAL TRACK MILEAGE IN ANY COMPLETED RAILROAD SYSTEM

Track Miles on Individual Railroads (See Table I)	Installations Grouped by Aggregate System Mileage on Two or More Railroads		All Systems
	1,000 Miles or Less	Over 1,000 Miles

TABLE III

SUMMARY OF RAILROAD SYSTEMS HAVING INSTALLATIONS AGGREGATING 1000 TRACK MILES OR MORE

Name of Railroad	Track Miles	Locomotives
New York Central Lines:		
B. & A.	485.82	238
C. C. C. & St. L.	376.9	100
M. C.	535.86	245
N. Y. C.	3,066.66	1,144
P. & L. E.	232.3	116
Total	4,697.54	1,843
Southern Railway System:		
C. N. O. & T. P.	492.7	179
Southern	2,919.34	693
Total	3,412.04	872
Pennsylvania System:		
Penna.	653.2	485
P. C. C. & St. L.	726.27	431
W. J. & S.	112.4	134
Total	1,491.87	1,050
Chicago & Northwestern System:		
C. & N. W.	1,050.0	365
C. St. P. M. & O.	(Exempt)	(Exempt)
Total	1,050.0	365
Total Above	10,651.45	4,130
Percentage of All Installations	53.9%	50.7%

Table III shows the details for these 11 railroads and the four systems to which they belong. At the present time (July, 1928) the Penna. System mileage is somewhat larger than here shown, by reason of additional voluntary installations. These four systems, the N. Y. C., Southern, Penna. and the C. & N. W., of course are the outstanding examples of the use of automatic train control today, representing 54 per cent of the total track mileage and 51 per cent of the locomotives equipped in the whole country as of March, 1928.

Average Installation

The average size of installation is shown in Table IV. For all installations the average is about 450 miles of track and 185 locomotives. Excluding the four systems having more than 1000 miles, the average is about 277 miles of track and 122 locomotives.

Status of I. C. C. Orders

Only five railroads have installations not completed in pursuance of both I. C. C. orders, but these are in progress. The details appear in Table V. It appears likely that all work will be 100 per cent complete by the close of 1928, and thereafter the new construction will be wholly voluntary unless, or until, the I. C. C. orders further installations.

TABLE IV

AVERAGE TRACK MILES AND AVERAGE NUMBER OF LOCOMOTIVES PER INSTALLATION

Number of Individual Railroads	Classification of Track Mileage in Any Complete Railroad System	Average Installation	
		Track Mileage	Number of Locomotives
33	1,000 Miles or Less	276.5	121.6
11	Over 1,000 Miles	968.3	375.5
44	All	449.2	185.0

Average miles of track equipped per locomotive equipped............2.43

Road Miles Equipped

Table VI shows the road miles equipped, under I. C. C. orders, with 1-track, 2-track, 3-track, 4-track, 5-track and 6-track installations. Double-track represents 57 per cent and single-track 35 per cent of the total road mileage, leaving only about 8 per cent with three or more tracks equipped.

Locations and Types of Installations

The location and the type of each installation made both pursuant to I. C. C. orders and voluntarily, are shown in Table VII. In compiling this table the installations are listed, in all cases, in the order corresponding to the first and second I. C. C. orders, followed by the voluntary installations, if any.

These installations are summarized by manufacturers and devices in Table VIII, arranged in the order of each manufacturer's aggregate track mileage equipped, with the greatest mileage at the top. The G. R. S. installations comprise about 58 per cent of the total track miles, the U. S. & S. Co. is represented by about 30 per cent, and the four remaining manufacturers comprise the balance of 12 per cent. No other manufacturers have any installations in road service, although a few are working with experimental installations, later mentioned.

TABLE V

STATUS OF INSTALLATIONS UNDER FIRST AND SECOND I. C. C. ORDERS

	First Order	Second Order
Railroads Installing Train Control.......	44	36

Reading

Tenant Roads

There are 19 tenant roads or lessees of track rights operating over roads equipped with automatic train control, with road distances ranging from about 3 miles up to 144 miles. These 19 tenant roads have 284 locomotives equipped for such operation. In one instance (C. & E. I.) there are 30 locomotives equipped with two different devices, Miller ramp and G. R. S. auto-manual. These 284 locomotives are not included in Table I, or any of the tables showing the details of Table I (II to IX, inclusive).

Types of Devices

Table IX shows a summary of all installations, grouped according to types of functions and types of devices. It appears very noteworthy that automatic train stops comprise about 83 per cent of the total mileage, of which 67 per cent is intermittent and 16 per cent is continuous inductive. The new code system of continuous inductive train stop, which is immune to foreign current or inductive interference, already comprises about 8.6 per cent of the total track mileage installed within the last two years. That is to say, slightly more than half of the present track mileage of continuous inductive train stop is equipped with the new code system and the remainder with the earlier type using steady 60-cycle rail current (with two exceptions) in the track circuit. Evidently from the latest reports the mileage of the code system is increasing, whereas the earlier type is not.

Automatic speed-control installations comprise about 17 per cent of the total track mileage, all of which was equipped under I. C. C. orders, except in one instance. Two-speed control includes 13 per cent and three-speed includes only 4 per cent of the total track mileage. Three-speed control, which is quite susceptible inductively, is still confined to the four roads which adopted it initially, namely the A., T & S. F., C. R. R. of N. J., N. & W., and Reading.

Installations made voluntarily have been equipped with the G. R. S. auto-manual (intermittent inductive) system of train stop, G. R. S. two-speed continuous inductive control (60 cycle), and the U. S. & S. Co. code system of continuous inductive train stop (100 cycle, interrupted). The G. R. S. installations of auto-manual comprise the largest mileage, the code system comes next, and the G. R. S. two-speed continuous control comes last with only one installation.

Future voluntary installations seem more likely to be made with the G. R. S. auto-manual and the U. S. & S. Co. code system than any of the other types; both are immune to foreign current interference.

*The National and Sprague systems are intermittent and inductive; the Regan and Miller systems are intermittent ramp.

Train Control Without Block Signals

Table X shows the railroads (two) at present operating installations of automatic train control without permissive wayside signals, more often termed automatic block signals. Both roads depend on continuous-type cab signals under continuous inductive control. Another road which has lately adopted this practice is the C. & N. W. This type of signal practice is novel and at present somewhat experimental. It represents only 8.8 per cent or less of the total track mileage equipped with automatic train control.

TABLE IX

SUMMARY OF TYPES OF DEVICES

Type of Function	Type of Device	Railroads	Track Miles	Locomotives
Automatic Train Stop	Intermittent Inductive	25	12,438.89	4,627
	Intermittent Ramp	2	852 7	300
	Continuous Inductive:			
	Steady A. C. Type	7	1,421.7	679
	Code System	6	1,700.87	1,332
	Continuous Inductive:			
Automatic Speed Control	2-Speed	7	2,587.76	933
	3-Speed	4	767.07	271
		44	19,764.99	8,142

Total Track Miles

TABLE X

INSTALLATIONS IN SERVICE WITHOUT PERMISSIVE WAYSIDE (AUTOMATIC BLOCK) SIGNALS

Railroad	Type of Control	Track Miles	Number of Locomotives
A. T. & S. F.	Continuous Inductive, 3-Speed	349.77	87
I. C.	Continuous Inductive, Train Stop	341.1	106
Total		690.87	193
Percentage of all Installations		3.5%	2.4%

Experimental Installations

Three installations have been in service experimentally, for test purposes, on the following railroads.

M. C.

The Continuous Train Control Corp. has been experimenting with the Clark System on 10 miles of one track between Jackson and Rives Junction, Mich., with one equipped locomotive. This system employs high-frequency current imposed on the existing signal circuits, for continuous control. It is understood to be somewhat similar to the carrier system, but no detailed technical information has been obtainable.

N. Y. C.

The Miller Train Control Corp. has an installation for development purposes on a division of the N. Y. C. between Detroit and Toledo. This company also has installations of two of its devices in regular service, the Miller ramp on the C. & E. I. and the Miller intermittent inductive system on the C. I. & L.

Mo. Pac.

The Automatic Electric Inc., manufacturer of Strowger automatic telephone equipment, in Chicago, has been testing the Hudd system on a short section of the Mo. Pac. Railway. The equipped engine has been temporarily dismantled.

The Hudd device is an intermittent inductive system. It is arranged to display three different conditions, namely, high, medium and low speeds, with cab signals, and can be applied as a train stop or as speed control. The present plans are to equip the Mo. Pac. between Omaha and Kansas City, some six months hence. As regards inductive susceptibility, it appears to be in the same class as other systems of the intermittent type.

Discussion of Inductive Susceptibility

There was a discussion of this subject in the Serial Report of the Inductive Coordination Committee on "Automatic Train Control," dated March, 1927 (Publication No. 267-21). That report covered the status of installations and devices as of August, 1925, or about four years ago at this time. The outstanding development since that date is the U. S. & S. Co. code system, which is a continuous inductive device, operating with 100-cycle current, coded by means of periodic interruptions of very much lower frequency.

As far back as three years ago it was already established that the continuous inductive three-speed 60-cycle system (U. S. & S. Co.) was very susceptible and actually experienced interference from 60-cycle commercial power systems adjacent to such an installation. Tests made on the Reading and the A. T. & S. F. established the cause of the susceptibility, and both the manufacturers and the railroads were cooperatively advised of the fact. Fortunately there have been no voluntary extensions of this system, but the situation with respect to the four roads now using this system, namely the A. T. & S. F., C. R. R. of N. J., N. & W. and Reading (see Table VII), are not substantially changed, except that the manufacturer made certain improvements in the loop receiver bar which helped matters to some extent.

The continuous inductive two-speed 60-cycle system of the U. S. & S. Co. and similar equipment used only as a continuous train stop is not very susceptible, but neither is it entirely immune. There is a potential type of danger, or false-clear failure, if a train should enter an occupied block, as under some conditions of inductive exposure the following (or rear) train might receive an erroneous high-speed or clear indication. Such a possibility was verified, experimentally, on a road installation. This difficulty appears to be inherent, and there is no apparent remedy except to adopt some different frequency of operating current, such as 100 cycles. No actual trouble in service has been reported from the installations now in operation, but we understand that at least one railroad is planning to change from 60 cycles to 100 cycles to avoid such possible failures.

The continuous inductive two-speed 60-cycle installations (G. R. S.) on the C. & N. W. from Chicago to Council Bluffs, Iowa, 1050 track miles, are claimed to be immune, and experience to date bears out the claim. There are numerous parallels with 60-cycle power lines on all three engine divisions, directly adjacent to the railroad. The Code system of two-speed 100-cycle continuous control on the Reading, 92 track miles, is claimed to be immune, and there is ample reason to accept the claim as true, although the operating experience to date is comparatively brief. These two roads, C. & N. W. and Reading, make an aggregate installation of 1142 track miles of two-speed continuous control, which appears to be immune to interference. The remainder of 1446 track miles of installations of two-speed control should be classed as doubtful, for reasons already stated. The latter installations are shown in Table VII and embrace the following five railroads:

D. L. & W.
L. & N.
O.-W. R. R. & N.
R. F. & P.
U. P.

Continuous inductive train stops embrace three kinds of devices, namely, the new Code system of the U. S. & S. Co., the devices using special frequencies, and those using 60 cycles. The installations of the Code system (on six roads) shown in Table VII embrace 1701 track miles, and this is being somewhat increased by recent voluntary installations. The 100-cycle system on the L. I. embraces 33 miles, and the 140-cycle system on the N. Y., N. H. & H. embraces 119 track miles, or together 152 track miles. These three systems can be classed as immune to interference, but the remainder of 1269 track miles of 60-cycle installations should be classed as doubtful, for the same reasons which apply in the case of two-speed 60-cycle continuous control. These installations of doubtful class are listed in Table VII, on the following five railroads:

B. & M.
C. M. St. P. & P.
I. C.
L. & N.
Penna.

The automatic train stops of the intermittent type, both inductive and ramp, appear to be wholly immune to any interference from adjacent power systems. Theory and experience seem to confirm this conclusion quite definitely

TABLE XI

TOTAL TRACK MILEAGE OF INSTALLATIONS CLASSIFIED BY INDUCTIVE SUSCEPTIBILITY

(As of March, 1928)

Type of Function	Type of Device	Classified by Inductive Susceptibility		
		Immune	Doubt-ful	Very Sus-ceptible
Automatic Train Stop	Intermittent Inductive	12,439	....	...
	Intermittent Ramp	853	....	...
	Continuous Inductive:			
	60-Cycle Systems	.....	1,269	...
	100 or 140 Cyc. Systems	152	....	...
	Code System, 100 Cycls.	1,701	....	...
Automatic Speed Control	Continuous Inductive:			
	2-Speed	1,142	1,446	...
	3-Speed	.....	....	767
Totals (Per	Cent of Grand Total)	82%	14%	4%

The status of all types of installations as to inductive susceptibility is summarized in Table XI This shows 82 per cent of the total track mileage as immune, 14 per cent doubtful, and 4 per cent very susceptible. It seems to be now recognized that the use of 60-cycle rail current is attended with certain hazardous possibilities from a railroad standpoint.

In this connection it is interesting to note that the second installation of three-speed 60-cycle continuous control on the A. T. & S. F., projected from Chillicothe, Ill., to McCook, Ill. (12.7 miles from Chicago), has been brought eastward only as far as Pequot, Ill. The unequipped section from Pequot to McCook, 44.5 road miles, traverses a region rather highly developed with power lines, including the Joliet-Chicago industrial district, a large steam generating station and switching station directly adjacent to the railroad near Joliet, and a very close parallel with the 44-kv. lines of the Chicago Sanitary District. It seems very questionable whether the three-speed 60-cycle train control can ever be made a safe and reliable device under such conditions as those just mentioned. The new Code system offers a very attractive remedy for such a situation, especially as it can be operated without permissive wayside signals, in accordance with A. T. & S. F. signal practice in the district already equipped.

Description of Code System

The so-called Code system of continuous inductive control was developed very recently by the U. S. & S. Co. in order to meet the requirements of both steam and electric propulsion, a-c. or d-c., and to overcome the effects of any kind of foreign current interference.

The Code system operates fundamentally with 100-cycle a-c. track circuits and tuned selective receivers on the locomotives. It can be adapted for use as a continuous train stop or for continuous speed control, with color-light cab signals. The system in use on the Penna. is a four indication automatic stop with the following indications:

1. Clear block (green signal, full speed).
2. Approach at restrictive speed (in a clear block, advancing toward a yellow signal).
3. Approach prepared to stop (in a yellow block, advancing toward a red signal).
4. Proceed with caution at low speed (in a red block, with train ahead in same block).

The 100-cycle current supplied to the track circuits is periodically interrupted, according to the following code, for the four preceding indications:

1. 180 interruptions per minute.
2. 120 interruptions per minute.
3. 80 interruptions per minute.
4. Steady 100-cycle current, or no current at all.

The cab signals change almost instantaneously with changes in track-circuit current, governed by the location and movements of the next train ahead. The locomotive equipment consists of a receiver bar just in advance of the front pair of truck wheels, electrical filter, 2-stage 2-tube amplifier, decoding transformer and master relay to amplify the coded impulses of low frequencies, and selective decoding relays which respond only to the low-frequency coded impulses. These relays control the color-light cab signals and the pneumatic brake application. Forestalling is provided for, if the engineman is alert and makes proper acknowledgment at each restrictive signal. The roadside apparatus includes a motor-driven interrupter, which supplies the coded 100-cycle current fed to the track circuit; there is one such interrupter at each point of track feed. Uncoded or steady 100-cycle current, or the absence of any such current, will both impose the low-speed condition on the receiver.

The 100-cycle track current can also be used for controlling the automatic block signals on the wayside, thus requiring but one source of power supply for both purposes, which can be supplied from a special 100-cycle transmission line located along the right-of-way. This has the further advantage that it tends to eliminate foreign-current interference with the block signal system. In order to obtain a clear understanding of the Code system, it will be of help to understand the fundamental principle of the a-c. track circuit for the automatic block signals, inasmuch as this track circuit serves a double purpose, namely. for both the block signals and the train control.

A-C. Block Signal Circuits

Whether or not wayside signals are employed in the automatic block system with superimposed train control, all other features of the block system must be employed in any event. The fundamental principle of the a-c. track circuit is, therefore, always employed, and it will facilitate the explanation of the train control to consider it first.

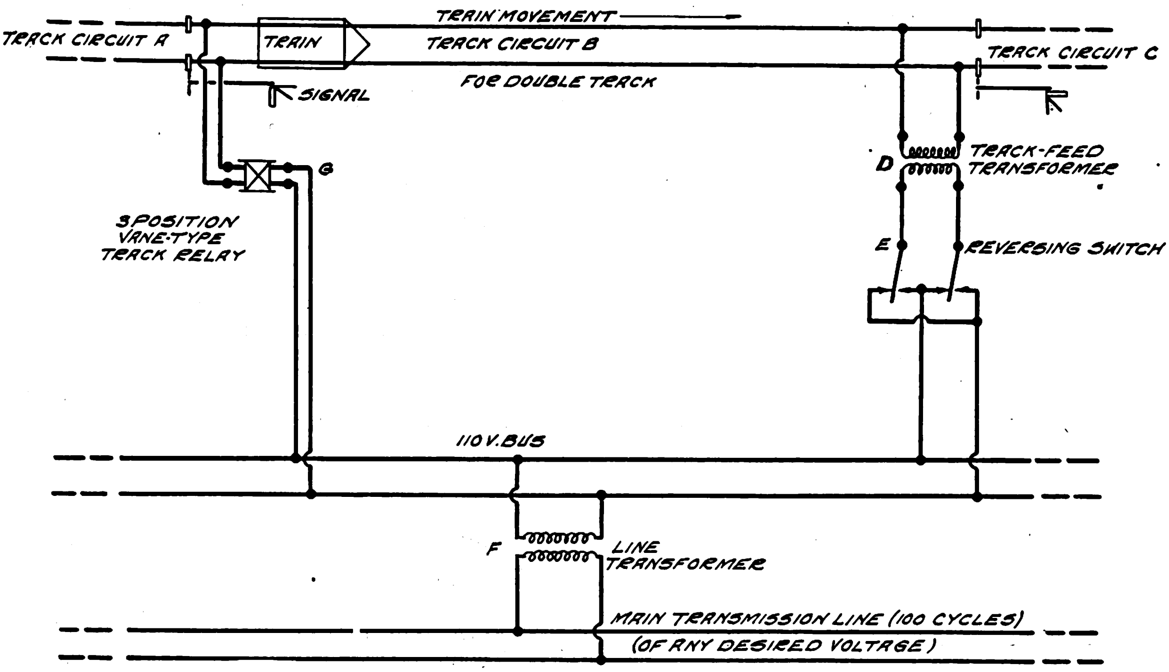

FIG. 1—Simplified Diagram of A-c. Wayside Circuits for Automatic Block Signals.

A simplified diagram of the a-c. track circuit is shown in Fig. 1, as applied to one track of a double-track road. Only one complete track circuit (B) is shown on the drawing, with a train moving in the normal direction of traffic. Assuming first that no train is present in block *B* or in block *C*, the conditions are as follows: The track transformer *D* is feeding the far end of track circuit *B*, so that energy will flow along the track against the direction of a normal train movement, thus energizing one of the windings of the track relay *G* at the entering (or approach) end of block *B*. The track relay G is a vane-type three-position relay, with its other winding normally energized from the 110-volt bus. When thus energized, the relay will cause the block signal at the entrance to block *B* to display green or clear. The reversing-switch *E* is controlled by the track relay of block *C*, as later explained. The line transformer *F* serves the 110-volt bus which extends along the right-of-way to feed the track circuits and the signal apparatus and lamps.

When a train is approaching in block *A*, a clear signal will be displayed at the entrance to block *B*. When the train enters block *B*, the axles will short the track circuit and de-energize one winding of the track relay *G*, which in turn will release and cause the signal at the entrance to *B* to turn red, and remain so until the train passes into block *C*. As the train enters *C*, the track relay in that block will be released, not only displaying a red signal at the entrance to *C*, but reversing the switch *E* and thus reversing the phase of the current in track circuit *B*. The latter will cause track-relay *G* to reverse, and thus display a yellow or restrictive signal at the entrance to block *B*, until the train passes beyond block *C*. When the train clears *C*, the track relay in *C* will pick up, thus restoring the reversing-switch *E* to normal, and changing the signal protecting *B* from yellow to green. At the same time the signal protecting *C* will change from red to yellow, as already explained.

Ordinarily the engineman must depend on the wayside signals of the automatic block system. However, when continuous inductive control is employed, with cab signals corresponding in color and indication to the wayside signals, the engineman will be instantly aware of any change in the signals, wherever he may be in a block, because the cab signals will change simultaneously. For example, assume a train in block *C*, and a train following, about to enter block *B* under a yellow or restrictive signal. When the second train advances say 1000 ft. in block *B*, assume that the leading train clears block *C*. Then the signal protecting *B* would change from yellow to green, if it were not for the rear train in *B*, but nevertheless the cab signal in the rear train will change instantly from yellow to green, allowing the engineman to increase speed without waiting until he has moved, say, 3000 ft. farther to the next wayside signal, and thus saving time.

Code System Track Circuits

In the Code system the track circuits are the same in principle as just explained, except that at each point of a-c. current feed to the track circuits there is a small motor-driven interrupter equipped to supply three different frequencies, namely, 180 interruptions per minute, 120 per minute and 80 per minute. This motor is started by a contact on the track relay at the entrance to the block, which closes when the track relay releases. This, of course, requires a control wire extending the whole length of the block. Thus the motor starts when a train enters the block and stops again when the train leaves it. The interrupter contacts are connected in series with the 110-volt supply to the reversing switch in such a way as to code the track current at the desired frequency, depending upon the signal indication at that location.

Fig. 2 shows the theory of the roadside circuits at a signal location on double track, for one track only. In tracing out the circuits, the contacts of each relay will be observed directly below the legend for the relay coils. The diagram, as shown, indicates the circuit conditions when no trains are present. When a train enters block *A*, the track relay releases and one of its center contacts (like the lower contact of *G* in the drawing) closes a circuit over a control wire which energizes relay *L*. This relay in turn starts the motor of the interrupter *M* and connects the latter with the 110-volt supply; it also clears the back contacts connecting the track-feed transformer *T* with the auto-transformer, for normal current supply to the track circuit, and impresses 110 volts on the transformer. By this means the 100-cycle a-c. current supplied to *T* is coded at 180 interruptions per minute, which conveys a clear or full-speed indication to the locomotive advancing in block *A*.

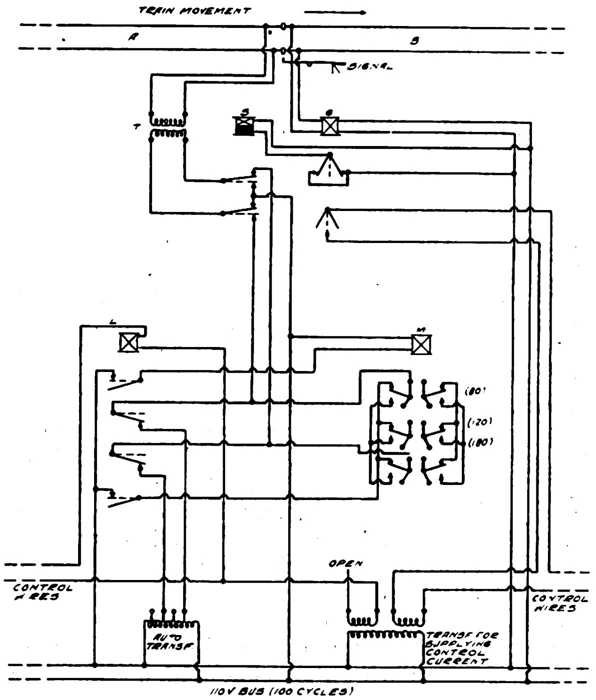

FIG. 2—SIMPLIFIED DIAGRAM OF A-C. WAYSIDE CIRCUITS FOR CODE SYSTEM OF TRAIN CONTROL

Now if block *B* were occupied by a train while another train is approaching in block *A*, the relay *G* would be released. This in turn would release the slow-acting relay *S*, thus reversing the phase of the track-circuit feed, and also impressing a periodicity of 80 interruptions per minute on the track circuit. The latter periodicity would impose the "approach prepared to stop" indication on the approaching train in block *A*.

When the train clears block *A*, the track relay of that block will pick up, but in reversed position, thus displaying a yellow signal. This will open the circuit of relay *L*, stop the interrupter *M*, disconnect the 110-volt supply to *M*, and restore the auto-transformer supply to *T*. Relays *G* and *S* will be released, and the interrupter in block *B* will be supplying coded track current at such frequency as the next signal, at the end of block *B*, may impose.

When the train clears block *B*, track relay *G* will pick up in reversed position, displaying a yellow signal; the contacts of *G* will re-energize *S*, and restore normal polarity to track circuit *A*, thus changing the signal at the entrance to *A* from yellow to green. When the train clears the next block beyond *B*, the signal from *B* will change from yellow to green.

The motor-driven interrupter is in operation only when a train is in the block to which it supplies track current, thus economizing in energy required.

If there is a train in block *B* and a second train follows it into this block, the second locomotive will receive no inductive pick-up and hence will have the low speed condition imposed on it. As soon as the leading train clears the block, the second locomotive will receive the "approach prepared to stop" indication, warning of a red signal at the next block.

When the feature of approach at restrictive speed is desired, as when the signals are less than braking distance apart, it can be provided very readily by adding another control relay and making use of the 120-per minute interruptions. This additional relay would be energized by relay *G* when in reversed position and would impose 120 interruptions per minute on *T*. The latter would impose the "approach at restrictive speed" indication on the locomotive advancing in block *A*, warning of a yellow signal at block *B*.

Code System Locomotive Circuits

The receiver bar on the locomotive is the same as that used in the 2-speed system of continuous inductive control, operated at 60 cycles. It is mounted just behind the pilot, but ahead of the front pair of truck wheels. The receiver coils constitute the moving secondary member of a loosely coupled transformer, of which the primary is the track circuit. The two receiver coils are so connected that their induced voltage is additive when current is flowing in opposite directions in the two rails of the track circuit; obviously no voltage would be induced by equal currents flowing in the same direction in the rails.

The locomotive circuits and electrical equipment are shown in Fig. 3. The induced receiver current passes through the filter, which excludes all frequencies more than 5 per cent above or below 100 cycles, and thence to the two-stage amplifier. Then the amplified current passes through the transformer primary, and the secondary current actuates the master relay, which is a d-c. polarized type and responds only to the frequency supplied by the wayside code transmitter, 180, 120 or 80 interruptions per minute. If the wayside current supplied to the

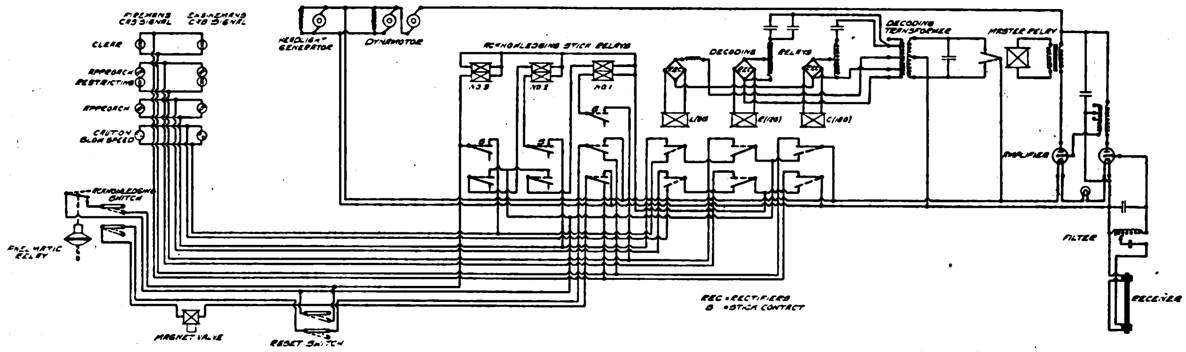

FIG. 3—SIMPLIFIED DIAGRAM OF LOCOMOTIVE CIRCUITS FOR CODE SYSTEM OF TRAIN CONTROL.

track circuit is steady 100-cycle current (not coded), or if there is no current in the track circuit, the master relay makes no response. The master relay is responsive to the increase and decrease in plate current from the amplifier, caused by the interrupted current induced in the receiver coil and in turn applied to the grid. Plate voltage is supplied from a dynamotor operated from the 32-volt headlight generator, which also supplies d-c. current for operating the train-control relays and associated apparatus.

The master relay impresses reversals of d-c. on the primary of the decoding transformer at the code frequency, and the secondary supplies a-c. at the code frequency to the rectifiers associated with the decoding relays. Selective operation of relay *C* is accomplished by means of a circuit tuned to 180 cycles per minute, with a low-voltage tap on the reactor. Relay *R* is similarly tuned for 120 cycles per minute. Relay *L* is not tuned, but has a reactor in series with the rectifier to cut down the current at the two higher frequencies. Thus at 180 cycles per minute, *C* and *L* will respond; at 120 cycles, *R* and *L* will respond; at 80 cycles, only *L* will respond; and at zero cycles all three relays will release.

All relays in Fig. 3 are shown in the position of responsiveness for 180 cycles per minute; the cab signals for "clear" are displayed, and there is a holding circuit through the two lower back-contacts of stick relay No. 1, the reset switch, the magnet valve, and the acknowledging switch.

When the coded track current changes from 180 to 120 interruptions per minute, relay *C* will release, relay *R* will be energized, and *L* will not change. This will extinguish the "clear" cab signal and display the "approach restricting" signal. If the engineman made no acknowledgment of the restrictive change in signals, the magnet valve would be deenergized and cause a service application of the brakes. Actuation of the acknowledgment switch will operate stick relays No. 3, No. 2 and No. 1 in cascade or sequence; No. 1 will close its own stick circuit and also close the circuit through the magnet valve, thus preventing a brake application, while No. 2 and No. 3 will release when the acknowledgment valve is released. This is termed forestalling a brake application.

When the coded track current changes from 120 to 80 interruptions per minute, relays *C* and *R* will be released, but *L* will not change. This will extinguish the "approach restricting" signal and display the "approach" signal. The stick circuit of stick relay No. 1 will be broken, and thus cause a brake application, but the actuation of the acknowledging switch will energize all of the stick relays as before, closing the stick circuit of No. 2, which in turn will hold No. 1 closed, and thus prevent a brake application.

When the track current is not coded, or if it is absent altogether, relays *C*, *R* and *L* will all be released. This will extinguish the "approach" signal and display the "slow speed" signal. It will also break the stick circuit of No. 2, but the actuation of the acknowledging switch will energize all of the stick relays as before, and the stick circuit of No. 3 will hold them all closed.

When the speed restrictions are removed in the reverse order, the stick circuits will be held automatically, and actuation of the acknowledging switch is unnecessary.

If an automatic brake application occurs, the pneumatic relay will open the circuit of the acknowledging switch, and it cannot be reclosed except by actuating the reset switch, which the engineman can reach only from the ground. This insures that an automatic application (which is not forestalled) will always perform its intended function and bring a train to a full stop.

The system above described is a four-indication automatic stop, but the number of indications may be only three, or even two, where the signal conditions will permit. It is also unnecessary, with cab signals, to retain the wayside signals, but this will leave a train without signal indications to regulate its movements if the cab signals should fail. The principles and equipment already described can be applied to speed control, but this introduces the necessity for an axle-drive contrifuge and imposes certain added complications in the locomotive equipment.

Code System Power Supply

Reliable central-station power, usually, at 60 cycles, may be obtained in nearly all parts of the country, but in unusually isolated locations self-starting, oil-electric generating sets may be employed. In order to obtain 100-cycle current without the complications incident to generator excitation with d-c., use is being made of induction-type frequency changers. The motor is a three-phase 60-cycle squirrel-cage unit, direct-connected to the wound rotor of the frequency changer, driving it in the direction of rotation which is opposite to the magnetic rotation of the stator field excited with three-phase 60-cycle current. The output frequency is the sum of the frequency of excitation and the frequency of rotation. The power input is partly electrical and partly mechanical, or approximately in the ratio of the component frequencies contributed by these two means. Thus a 10-kw. frequency changer excited with 60-cycle current requires only a 4 kw. motor to drive its rotor, from which the electrical output is delivered. The N. Y., N. H. & H. R. R. is using frequency-changer sets designed for a rated output of 5 kv-a., 4.5 kw., 0.9 power factor and 1200 r.p.m.

Where more power is required, as in the installations on the P. C. C. & St. L. Ry., where a-c. signals are employed, use is being made of motor-generator sets consisting of a 75-h.p., 2200-volt, 3-phase, 60-cycle squirrel cage motor, direct-connected to a 60-kv-a., 0.80-power factor, 220-volt, single-phase, 100-cycle generator with a direct-connected exciter.

It is necessary to provide a 100-cycle transmission line along the railroad right-of-way to supply the track circuits and associated control circuits; in some cases it may also supply a-c. signals, as on the Penna. road. Customary line voltages are 550, 2200, 4400 and 6600 volts. Power sources are usually located every 20 to 25 miles, where small automatic substations are installed, sometimes with a reserve source for emergency. The line is sectionalized between substations, so that it can be fed from either end, or cut through, and automatic features are provided for throw-over in the event of the failure of any individual source of supply. Close regulation of voltage and frequency is necessary for the proper operation of the train control.

Installations

In Table VII there are listed six installations of the Code system of train stop, on the C. R. R. of N. J., L. I., N. Y., N. H. & H., Penna., P. C. C. & St. L. and W. J. & S.; also one installation Code system of 2-speed control on the Reading. In addition the Penna. installation from Baltimore to Harrisburg in order to be interchangeable with the others, is being changed to the Code system. The aggregate installations (five) on the entire Penna. system will comprise 611.5 road miles, 1491.8 track miles and 1159 locomotives. These installations will be interchangeable with those on the C. R. R. of N. J., L. I., N. Y., N. H. & H. and Reading.

I. C. C. Hearings on Automatic Train Control

Division 6 of the I. C. C. held hearings on automatic train control and block signals in Washington, D. C., on Feb. 27-29 and April 23-30, 1928, and some of the testimony presented is of interest. The reports of these hearings are very briefly abstracted in what follows, by railroads (taken from "Railway Signaling").

C. & E. I. Miller ramp. No accidents. Sleet on ramps has caused some undesirable stops. They consider their present installation sufficient, under existing conditions.

B. & O. G. R. S. intermittent inductive. No accidents. Still have too many unnecessary stops, due to various faults, but these are being reduced. Stops are sometimes caused by metal masses on the roadway. Reading locomotives with U. S. & S. control also operate on B. & O. tracks with G. R. S. control. Are positively opposed to cab signals. Regard automatic train control wholly unnecessary.

Southern. G. R. S. intermittent inductive. Few undesired stops. Two accidents. System is satisfactory. Have made voluntary installations on 17 engine divisions.

C. & N. W. G. R. S. 2-speed continuous inductive. Use cab signals and have removed roadside block signals. No trouble from foreign currents and few undesired stops. Have had one false-clear operation. Equipped one engine division voluntarily.

I. C. U. S. & S. Co. continuous inductive stop. Use cab signals but no wayside signals. Tried speed control, but was rejected because too complicated. No accidents. Seven false-clear operations, but not chargeable to the system. Their enginemen greatly favor the cab signals.

A. T. & S. F. U. S. & S. Co. 3-speed continuous inductive. Use cab signals but no wayside signals. The Union system was adopted after considering the first trial of it on the Lewistown branch of the Penna. Enginemen like the system. Management would prefer to spend money for block signals instead of train control. Are extending the block signals.

Mo. Pac. National intermittent inductive. No false-clear operations and few undesirable stops. Has deferred need for second track. Need more block signals rather than train control.

C. R. I. & P. Regan ramp. No more trouble from ice and snow than with semaphores. Have had five false-clear failures, but none recently. Have economized by eliminating unnecessary stoppage of trains at signals.

N. Y. C. G. R. S. intermittent inductive. Have very large mileage now equipped, including numerous voluntary installations. No light signals are used in the cabs, and enginemen prefer not to have them. One false-clear indication. Electric division from New York to Harmon is yet to be equipped. Penna. and C. & E. I. locomotives are operated over N. Y. C. tracks with no trouble. N. Y. C. considers it has made a great improvement.

C. B. & Q. Sprague intermittent inductive. General results are very good. No false-clear failures. Need uniformity or interchangeability as between different roads. No sweeping order should be issued by I. C. C.

Penna. Operated U. S. & S. Co. 3-speed continuous inductive on Lewistown branch from July, 1923, until January, 1926, with cab signals but no wayside signals. Next installed U. S. & S. Co. continuous inductive stop from Baltimore to Harrisburg, but are now changing it to the Code system, 100-cycle interrupted current, with four-indication cab signals. The Code system is now in service on four other divisions, and the installations are not only identical with each other, but with the L. I., C. R. R. of N. J., Reading and N. Y., N. H. & H., so that locomotives will be interchangeable.

Code system was developed to overcome effects of a-c. or d-c. propulsion of trains and a-c. or d-c. track circuits for signals. Analysis of their accidents show that cab signals would have prevented the most serious accidents. Their enginemen are greatly in favor of visual (color-light) cab signals. Will install Code system on New York division this year, with two four-indication cab signals on each locomotive, one for the engineman and one for the fireman. Will also equip other main-line divisions with similar equipment as rapidly as their finances will permit, without orders from the I. C. C. Have had a few false-clear failures, mostly not chargeable to the system. Do not approve of eliminating roadside block signals on a busy road.

Central of Georgia. No passenger killed in 12 years in any accident preventable by automatic train control. Highway grade-crossing protection requires large expenditures. Train control not justified at this time.

C. I. & L. Miller intermittent inductive. No passenger killed in a collision since 1897 and none injured since 1915. Do not need any more automatic train control.

C. M. St. P. & P. U. S. & S. Co. continuous inductive stop. Report satisfactory results. No trouble from stray currents. Use the cab signal and favor it. Consider that the experimental stage is not yet past.

C. G. W. Has no train control. It makes expenditures for extension of its automatic block signals.

D. L. & W. U. S. & S. Co. 2-speed continuous inductive. Automatic roadside signals are reasonably adequate and far more economical than automatic train control. Accident records for seven years show possible saving of $14,000 by automatic train control.

D. & R. G. W. This road is mountainous and crooked. Overheated wheels offer more danger than collisions. Have made large expenditures for block signals, including the appropriation for this year.

C. & O. U. S. & S. Co. intermittent inductive. Have experimented with automatic train control since 1916. Present system is satisfactory. They make large expenditures for grade crossing elimination and for signals. Present need for additional automatic wayside signals is so important that no order should be issued at this time for more train control.

Erie. G. R. S. intermittent inductive. In 16 years past there was no death in a train collision which could have been prevented by automatic train control.

Gt. Nor. Sprague intermittent inductive. Have never killed a passenger in a train accident in automatic block signal territory. Make large expenditures for signals.

Gr. Trunk Western. Are installing automatic block signals this year, at a large expenditure, on 50 miles of double track.

St. L.-S. F. National intermittent inductive. They do not believe the results of their installation justify its cost. Will install automatic block signals on 120 miles this year.

M. K. T. Asked to be relieved from any order of the I. C. C. as not justified at present. Will continue to make large expenditures for automatic block signals.

N. Y., N. H. & H. U. S. & S. Co. general continuous inductive stop and Union Code System. Not opposed to train control, but think that equivalent expenditures for other purposes will provide greater safety. Have no record that train control has prevented an accident. No passengers killed in train accidents since 1916.

Nor. Pac. Sprague intermittent inductive. Have large investment in automatic block signals, but additional train control would not be justified.

St. L.-S. W. Has not reached a stage of development where train control is required or justified.

S. A. L. Now has 500 miles of automatic block signals. Better to extend signals than install train control, but cannot get money to do both. Asks to be exempted from I. C. C. orders.

So. Pac. National intermittent inductive. Has the largest road mileage of automatic block signals of any road in the country, and it is being extended. Has no traffic conditions which justify automatic train control.

Tex. & Pac. Already has extensive block signal system, which is being extended. Asks that the I. C. C. impose no order upon it.

L. & N. U. S. & S. Co. 2-speed continuous inductive and Union continuous inductive stop. Have made large expenditures for block signals and other safety devices, and will continue to extend block system. Train control is neither necessary nor desirable at this time.

U. P. U. S. & S. Co. 2-speed continuous inductive. Has large installation of automatic block signals covering all main lines, which will be extended to secondary lines. Their present installations of train control are not needed, but are supplying valuable experience. When traffic conditions justify it, they are ready to go ahead with voluntary installations.

N. & W. U. S. & S. Co. 3-speed continuous inductive. Have 90 per cent of their passenger track mileage and 72 per cent of mileage now equipped with automatic block signals. They desire to be permitted to exercise their best judgment as to expenditures.

Reading. U. S. & S. Co. 3-speed continuous inductive and Code system. They urge the postponement of any further I. C. C. requirements until more experience has been had with the various types as to interchangeability, which affects them rather seriously.

Summary of Hearings

Railroad safety is on the increase for both passengers and employes. Last year's safety record was excellent and far above the previous year. Highway grade crossings present a serious problem. Train control installations have already cost the railroads $22,395,000 under I. C. C. orders. Some of the railroads regard train control as still in the experimental stage; others stress the need for uniformity and interchangeability in types of installations. Railroads oppose any additional formal orders by the I. C. C. for automatic train control or other safety devices at this time and desire freedom of judgment in making expenditures to secure the best and most satisfactory results. This was substantiated by most of the representatives of 168 respondent railroads at the hearing and by the official spokesman for the A. R. A.

STATE LAWS RELATING TO THEFT OF ELECTRIC CURRENT

As a result of frequent requests for information concerning State laws relating to the theft of electric current, the Meter Committee, Engineering National Section, N. E. L. A., has, through its Contact and General Procedure Subcommittee, had compiled by the General Counsel for the Association the following State laws covering the subject.

In the following pages is set forth the text of the current laws of each State (and the District of Columbia), together with pertinent comment from court and commission decisions in leading cases. Although the Committee's primary interest is in laws relating to the theft of electric current, enactments and opinions concerning the theft of other public utility services have been included.

STATES THAT HAVE LAWS COVERING ILLEGAL USE OF ELECTRICITY, GAS, WATER, ETC.

1. Alabama—Gas, Steam and Electricity.
2. Arizona—Gas, Water and Electricity.
3. Arkansas—Gas and Electricity.
4. California—Gas and Electricity.
5. Colorado—Gas and Electricity.
6. Connecticut—Gas and Electricity.
7. Delaware—Electricity and Gas.
8. District of Columbia—Electricity only.
9. Florida—Electricity, Gas and Water.
10. Georgia—Gas and Electricity.
11. Idaho—Electricity and Gas.
12. Illinois—Gas, Water and Electricity.
13. Indiana—Gas and Electricity.
14. Iowa—Electricity, Water, Steam Heating and Gas.
15. Kansas—Gas, Electricity and Oil.
16. Kentucky—Electricity only.
17. Louisiana—Gas, Electricity and Water.
18. Maine—Gas, Electricity and Water.
19. Maryland—Gas and Electricity.
20. Massachusetts—Gas and Electricity.
21. Michigan—Water, Steam, Electricity and Gas.
22. Minnesota—Electricity only, but refers to prepay meters and pay telephones.
23. Mississippi—Electricity, Water and Gas.
24. Missouri—Gas and Electricity.
25. Montana—Gas and Electricity.
26. Nebraska—Electricity, Gas and Water.
27. Nevada—Water, Gas, Electricity or Power.
28. New Hampshire—Electricity only.
29. New Jersey—Gas and Electricity; Water.
30. New Mexico—Electric Transmission Lines, or leakage or loss in any manner therefrom.
31. New York—Gas, Electricity, Telephone or Telegraph.
32. North Carolina—Gas and Electricity.
33. North Dakota—Gas and Electricity.
34. Ohio—Gas and Electricity.
35. Oklahoma—Gas only.
36. Oregon—Gas and Electricity.
37. Pennsylvania—Electricity, Heat, Power, Gas and Water.
38. Rhode Island—Gas, Water and Electricity.
39. South Carolina—Light, Heat, Power and Gas.
40. South Dakota—Gas, Water and Electricity.
41. Tennessee—Gas, Electricity, Telephone and Telegraph Wires, and current used in connection with Light and Power.
42. Texas—Electricity, Gas and Water.
43. Utah—Gas and Electricity.
44. Vermont—Gas, Electricity and Water; Heat and Power
45. Virginia—Gas and Electricity.
46. Washington—Gas, Electricity, Steam and Water.
47. West Virginia—Gas, Electricity and Water.
48. Wisconsin—Gas, Electricity, Water and Steam.
49. Wyoming—Gas and Electricity.

CRIMINAL CODE—REVISED STATUTES, SUMMARIZED

Alabama

Ten Sections—covering all offenses concerning Gas, Steam and Electricity. Penalty: Fine not less than $10.00 nor more than $500.00, or imprisonment in the county jail at hard labor not less than ten days nor more than six months.

Arizona

Four Sections—covering Gas, Water and Electricity. Penalty not exceeding six months; fine not exceeding $300.00, or both.

Arkansas

Four Sections—covering Gas and Electricity. Penalty: Fine not less than $5.00 nor more than $100.00, or by imprisonment not exceeding one year, or both.

California

Three Sections—covering Gas and Electricity. Penalty: Fine not exceeding $500.00 or imprisonment in jail not exceeding six months, or both.

Colorado

Twelve Sections giving in great detail various methods of detection of Gas and Electricity, and what constitutes prima facie evidence. Penalty: thirty to ninety days or $50.00-$300.00, or both. Section covers tampering with electric wires in any manner.

Connecticut

Two Sections—covering Gas and Electricity. Penalty: Fine not more than $50.00 or imprisonment not more than ninety days, or both.

Delaware

Two Sections—covering Electricity and Gas. Penalty: Not exceeding $50.00 or three months' imprisonment, or both.

District of Columbia

One Section—Electricity only. Penalty not exceeding $1,000.00 or imprisonment not exceeding one year, or both.

Publication No. 289-7, Serial Report, Meter Committee.

Florida

Two Sections—covering Electricity, Gas and Water. Penalty not exceeding $500.00 or imprisonment not exceeding one year.

Georgia

Three Sections—Gas and Electricity. Penalty: Female, not exceeding twelve months or fine not exceeding $1,000.00. Male, imprisonment; convict work on public roads not more than twelve months; fine not exceeding $1,000.00. Punishment seems to be discretionary with judge as to whether a sentence shall be to the penitentiary or to the State Farm.

Idaho

Six Sections. Principal and anyone assisting or abetting equal guilt. Penalty: Not exceeding $300.00; imprisonment not exceeding six months, or both. Covers Electricity and Gas.[1]

Illinois

One Section—covering Gas, Water and Electric Current. Penalty: Not exceeding three months or fine not exceeding $250.00, or both.[2]

Indiana

Five Sections—Gas and Electricity. Fine not exceeding $100.00; imprisonment not exceeding one year, or both. The Indiana law seems to have been tested on more than one occasion by appeal to the Supreme Court, who appears to have upheld the Act in every particular.

Iowa

Three Sections—Electricity, Water, Steam Heating and Gas. Penalty: When property stolen exceeds $20.00, imprisonment in penitentiary not more than five years, nor in the county jail not more than one year; nor fined not more than $1,000.00, or both. Where value stolen does not exceed $20.00, fine not exceeding $100.00 and imprisonment in county jail not exceeding thirty days.

Kansas

Three Sections—Gas, Electricity and Oil. These Sections are general and cover tampering with telephone, telegraph, electric transmission lines, wires and cables, pipes on surface or in ground, etc. Penalty under Section No. 17, fine not exceeding $500.00 and imprisonment in county jail not exceeding one year, or both. Under Section No. 55-109, which appears to refer particularly to Oil and Gas, fine not less than $25.00, nor more than $100.00.

Kentucky

Five Sections—covering Electricity. Penalty: $5.00 to $500.00 or imprisonment ten days to one year, or both.

Louisiana

Electricity and Gas. Four Acts, consisting of twenty sections, defining evidence. Making tampering or diversion a misdemeanor. Penalty varies from ten days to six months imprisonment in Parish Prison. Sentence may be applied to principal and those convicted of assisting in act.

Maine

One Section—Gas, Electricity and Water. Penalty: Fine not exceeding $100.00, imprisonment not more than one year, or both.

Maryland

Three Sections—covers Gas and Electricity. Penalty: Imprisonment not exceeding six months; fine not exceeding $500.00, or both.

Massachusetts

General Laws of 1921—Two Sections—covers Gas and Electricity. Penalty not more than $100.00 fine or imprisonment not more than one year, or both.

Michigan

Three Sections—covers Water, Steam, Electricity and Gas. Penalty: Where value stolen does not exceed more than $25.00, fine not exceeding $100.00 or imprisonment not more than ninety days, or both. If value of commodity stolen exceeds $25.00, fine is not to exceed $1,000.00 and imprisonment in the State penitentiary for not less than three months nor more than three years, or both. The provision is written in the law which states that criminal prosecution does not impair the right of the company full compensation in damages by a civil suit; also defines what constitutes prima facie evidence as to control and occupancy of the premises where offence was committed.

Minnesota

One Section—covers Electricity only, but refers to prepayment; electric prepay meters and pay telephones fraudulently obtaining the use of either. Penalty not exceeding three months in jail; fine not exceeding $100.00.[3]

---

[1] Idaho has a special section known as "CH-208—Idaho Session Laws 1921," section No. 2 of which permits any corporation selling illuminating gas who shall have probable cause to believe that any person, etc., is violating the provisions of their meter cheating act, shall, upon making affidavit required in, and complying with all the provisions of Chapter No. 332, of Title No. 61, of the Compiled Statutes, be entitled to have a search warrant issued to it and served in the manner provided in Chapter No. 332, of Title No. 61.

This provision will prove of value in detecting meter cheating. Many good and sufficient reasons can be given as "probable cause" when application is made for a search warrant. In Louisiana today, unless permission is granted by the owner to enter a house, it is impossible for company inspectors to gain admission thereto without a long tedious process of law, and by the time the suspected person is summoned into court to show cause why a search warrant should not be issued, all evidence of guilt, of course, is removed.

[2] In the interesting case of Woods vs. The People, 222 Ill. 293-298, the amount of gas stolen, the jury found, exceeded $15.00 in value and the defendant was sentenced to the penitentiary for an indeterminate period. On a writ of error, the case was appealed to the Supreme Court, who affirmed the judgment of the jury.

[3] In examining the Digest of the Minnesota Law, Section No. 8946 particularly refers to Electricity, but reference is made to the case of the State of Minnesota vs. Wellman, 34 Minn. 221, 222, in which defendant was charged with larceny of 500 feet of illuminating gas, valued at $12.50. He was found guilty of larceny and sentenced accordingly.

Reference is made to this case, as Section No. 8946 apparently only refers to Electricity, so we can assume that the Minnesota law covers both Gas and Electric meter cheaters.

Mississippi

General laws of 1922. One Section—covers Electricity, Water and Gas. Penalty: Fine $10.00 to $100.00; imprisonment three months, or both.

Missouri

Three Sections—covers Gas and Electricity. Penalty: Fine not less than $50.00, nor more than $500.00; imprisonment not less than three months, nor more than twelve months, or both; defines in detail what constitutes prima facie evidence and intent to defraud.

Montana

Two Sections—covers Gas and Electricity. Penalty: Fine not exceeding $500.00 or imprisonment not exceeding six months, or both.

Nebraska

Six Sections—covers Electricity, Gas and Water. Penalty: Fine not less than $50.00 nor more than $300.00; imprisonment not less than thirty days nor more than ninety days; defines prima facie evidence of guilt.

Nevada

One Section No. 6733 with four divisions; defines tampering with the purveyance of flumes, ditches, conduits, reservoirs, wires or any other apparatus used in connection with Water, Gas, Electricity or Power, or destroys or detaches or disconnects or damages in any manner any apparatus that purveys above commodities; fine not exceeding $500.00; imprisonment not to exceed six months, or both.

New Hampshire

One Section—Electricity only. Penalty: Not to exceed $300.00 in a criminal case and in a civil case to pay treble damages should an action be taken to recover under a civil action.

New Jersey

Three Sections—covers Gas, Electricity and Water. Penalty: Fine not exceeding $1,000.00, imprisonment with or without labor not exceeding three years, or both; reserve right to recover damages by civil action.

New Mexico

One Section—covers Electric Transmission lines, or leakage or loss in any manner therefrom. Penalty: Not exceeding $100.00 or imprisonment not exceeding thirty days, or both.

New York

Three Sections and Subdivisions thereof—covers tampering with any meters, automatic vending machines, slot machines, coin box telephones, telephone machines or any other machine used in connection with the purveyance of Gas, Electric Current, Telephone or Telegraph. Penalty: Fine not more than $250.00 or imprisonment not more than six months, or both; gas or electric current or steam; imprisonment in county jail or penitentiary not more than one year and fine not more than $500.00, or both.

North Carolina

Three Sections with Subdivisions—covers Gas and Electricity. Penalty: Imprisonment for not less than four months, not more than ten years; fine (amount not stated).

North Dakota

Three Sections—covers Gas and Electricity. Penalty: Not exceeding one year in jail and fine not exceeding $500.00, or both.

Ohio

Four Sections—covers Gas and Electricity. Penalty: Not less than $25.00 nor more than $300.00; imprisonment not more than thirty days, or both.

Oklahoma

Two Sections—covers gas. Penalty: Not exceeding one year or fine not exceeding $500.00, or both. These sections cover larceny of Gas only; Electricity is not mentioned.

Oregon

One Section with nine Subdivisions—covers Gas and Electricity, and any person that aids and abets and assists. Penalty: Fine not less than $50.00 nor more than $500.00, or imprisonment in jail not less than thirty days, nor more than one year, or both.

Pennsylvania

Four Sections—covers Electric Light, Heat, Power, Gas and Water. Penalty: Imprisonment not exceeding one year nor fine not exceeding $1,000, or both, for electricity, light, heat and power. For gas and water fine not exceeding $300.00 or imprisonment not exceeding three months, or both.

Rhode Island

Three Sections—covers Gas, Water and Electricity. Penalty: Not exceeding thirty days; fine not exceeding $100.00.

South Carolina

Four Sections—covers Light, Heat, Power and Gas. Penalty: Fine not exceeding $100.00 and imprisonment not exceeding thirty days, or both.

South Dakota

Three Sections—covers Gas, Water and Electricity. Penalty: Fine not exceeding $100.00, imprisonment not exceeding sixty days, or both.[4]

---

[4] The South Dakota Revised Code of 1912, Section No. 4398, provides that any person employed to read meters who knowingly reports to his employer that any consumer of Gas, Water, or Electricity has used a greater amount of Gas, Water or Electricity than the amount actually used by said consumer, shall be sentenced in the County Jail not exceeding three months or by fine not exceeding $250.00, or both. Any person who knowingly collects from a consumer a greater amount than is actually used shall be punished by a fine not exceeding $500.00. This provision is unique as it does not appear in any other laws so far examined.

Tennessee

Four Sections—covers Gas, Electricity, Telephone and Telegraph Wires and Current used in connection with Light and Power. Penalty not less than $5.00 nor more than $50.00, or imprisonment in the county workhouse or jail not less than ten days nor more than twelve months, or both.

Texas

One Section—covers Electricity, Gas and Water. Penalty: Fine not less than $25.00 nor more than $100.00, and defines what constitutes prima facie evidence.

Utah

Three Sections—Gas and Electricity. Penalty: Imprisonment in jail not exceeding six months or by fine not less than $300.00, or both; but in case a corporation is convicted of any offense, such corporation is punishable by a fine not exceeding $1,000.00.

Vermont

Three Sections—covers Gas and Electricity. Penalty: For Gas, Electricity and Water, not more than $100.00, or imprisonment not more than one year, or both. Penalty for interfering with Electric Light, Heat or Power, or obstructing its use in any way, imprisonment not more than two years, or be fined not more than $300.00, or both; recovery is made in an action of tort for breaking into, damaging or interfering with a meter properly registering, or appliances attached to or connected with wires, pipes, mains, etc., shall be imprisoned not more than three months or pay more than $100.00, or both.

Virginia

Two Sections—covers Gas and Electricity. Penalty: Fine not exceeding $500.00, or imprisonment in jail not exceeding twelve months, or both.

Washington

Two Sections with numerous Subdivisions—covers Gas, Electricity, Steam and Water. Penalty: Imprisonment not more than ninety days, nor fine not more than $250.00.

West Virginia

Two Sections—covers Gas, Electricity and Water. Penalty: Not exceeding twelve months in jail, or by fine not exceeding $1,000.00, or both.

Wisconsin

One Section—covers Gas, Electricity, Water and Steam. Penalty: Fine not exceeding $500.00, or imprisonment in the county jail not more than one year, or both. In the event the amount stolen does not exceed $20.00, punishment shall be by imprisonment in jail for not more than three months, or by fine not exceeding $100.00.

Wyoming

Eight Sections—covers Gas and Electricity. Penalty: Not less than $50.00 nor more than $300.00, or by imprisonment in jail for not less than thirty nor more than ninety days, or by both.

STATUTES AND COURT AND COMMISSION DECISIONS

Alabama Criminal Code of 1923

Offenses Concerning Gas, Steam or Electricity

Sec. 4294.—No person shall connect a tube, pipe, wire or other instrument or contrivance with a pipe or wire used for the conducting or supplying of illuminating gas, fuel gas, electricity or steam, in such a manner as to supply such gas or electricity or steam to any burner, orifice, lamp, motor or pipe where the same is or can be burned or used, without passing through the meter or instrument provided for registering the quantity consumed.

Sec. 4295.—No person shall destroy, alter or prevent the action of a meter or other instrument used to measure or register the quantity of illuminating gas, fuel gas, electricity or steam, consumed in a house or apartment, or at an orifice, burner, lamp, motor or pipe, or by a consumer or other person, or detach or disconnect such meter or other instrument.

Sec. 4296.—No person shall, in any manner whatever, change, extend, or alter any service or other pipe, wire or attachment of any kind, connecting or through which artificial gas, electricity or steam is furnished from the gas mains or pipes or wires or source of supply, of any person, company or corporation.

Sec. 4297.—No person shall make any connections or reconnections with the gas mains, service pipes or wires of any person, company or corporation furnishing to consumers artificial gas, electricity or steam, or turn on or off in any manner, or in any manner interfere with any valve or stopcock or other appliance belonging to such person, company or corporation and connected with its gas mains, service or other pipes or wires.

Sec. 4298.—No person shall retain possession of or refuse to deliver any meter or meters, lamp or lamps, or other appliances which may be or may have been loaned or rented by any person, company or corporation for the purpose of furnishing gas, electricity or steam through the same, nor sell, loan or in any manner dispose of the same to any person or persons other than the said person, company or corporation entitled to the possession of the same.

Sec. 4299.—No person shall set on fire any gas escaping from broken or leaking mains, pipes, valves or other appliances used by any person, company or corporation in conveying gas to consumers, or interfere in any manner with the pipes, mains, gate boxes, valves, stopcocks, wires, cables, conduits or any other appliances, machinery or property of any person, company or corporation engaged in furnishing gas, electricity or steam.

Sec. 4300.—Any person who shall maliciously, or with intent to injure or defraud, do or commit, or shall aid or abet in the commission of any of the acts forbidden in this chapter, shall be guilty of a misdemeanor, and upon conviction shall be fined not less than $10 nor more than $500, and may also be imprisoned in the county jail, or at hard labor for the county, for not less than ten days nor more than six months, one or both at the discretion of the judge or jury trying the case.

Sec. 4301.—Proof that any of the acts specified in this chapter was done on the premises in the possession of the accused, or that the accused received the benefit of any such act or acts, shall be prima facie evidence that the accused committed such act, or aided or abetted in the commission thereof maliciously, or with intent to injure or defraud.

Sec. 4302.—Every person, company or corporation now engaged or hereafter engaging in the business of furnishing natural or artificial gas for heating, illuminating or other purposes, to be used and paid for by patrons by meter measure, shall furnish to each and every patron a meter properly tested and in good order, and shall arrange such meters so that the patrons can, at any time, see the meter dial and ascertain how much gas he is consuming, and how much he is liable to pay for.

Sec. 4303.—Whoever knowingly constructs, or uses, or furnishes to gas consumers to be used, any false meter provided for measuring and registering the quantity of gas consumed by any person under a contract with any gas company, shall, on conviction, be fined not less than $10 nor more than $100.

Arizona Revised Statutes 1913 (Penal Code)

Larceny

Sec. 495.—Every person who, with intent to injure or defraud, makes or causes to be made, any pipe, tube or other instrument, and connects the same, or causes it to be connected, with any main, service pipe or other pipe for conducting or supplying illuminating gas, in such manner as to supply illuminating gas to any burner or orifice, by, or at which illuminating gas is consumed, around or without passing through the meter provided for the measuring and registering the quantity consumed, or in any other manner so as to evade payment therefor, and every person who, with like intent, injures or alters any gas meter or obstructs its action, is guilty of a misdemeanor.

Sec. 496.—Every person who, with intent to injure or defraud, connects or causes to be connected, any pipe, tube or other instrument, with any main, service pipe or other pipe, or conduit, or flume for conducting water, for the purpose of taking water from such main, service pipe, conduit or flume, without the knowledge of the owner thereof, and with intent to evade payment therefor, is guilty of a misdemeanor.

Sec. 497.—Every person who, with intent to injure or defraud, makes or causes to be made by wire, or otherwise, any connection with any main or service line for conducting or supplying electricity in such manner as to procure electricity without its passing through the meter provided for the measuring and registering of the quantity consumed or in any other manner so as to avoid payment therefor, or any person who, with like intent, injures or alters any electric meter or obstructs its action, is guilty of a misdemeanor.

Sec. 19.—Except in cases where a different punishment is prescribed by this code, every offense declared to be a misdemeanor is punishable by imprisonment in a county jail not exceeding six months, or by a fine not exceeding $300, or by both.

Arkansas (Crawford & Moses) Digest of Statutes 1921

Criminal Law

Sec. 2480.—It is hereby declared to be unlawful for any person or persons to set on fire any gas escaping from wells or from broken or leaking mains, pipes, valves or other appliances, used by any person, company or corporation in conveying gas to consumers, or to tap any pipe or main for the purpose of taking and stealing gas therefrom, or to interfere in any manner with wells, pipes, mains, gate boxes, valves, stopcocks or other appliances, machinery or other property of any person, company or corporation engaged in furnishing gas to consumers, unless employed by, and acting under the authority and direction of, such person, company or corporation furnishing gas to consumers. Act, May 6, 1905, p. 635, sec. 1.

Sec. 2481.—It is hereby declared to be unlawful for any person in any manner whatever, to change, extend or alter, or to cause to be changed, extended, or altered, any service or other pipe or attachment of any kind, by or through which natural or artificial gas is furnished from the gas mains or pipes of any person, company or corporation without first securing from said persons, company or corporation written permission to make such change, extension or alteration. Id. sec. 2.

Sec. 2482.—Any person violating any provision of secs. 2480 and 2481 of this act shall, upon conviction, be fined in any sum not less than $5 nor more than $100 for such offense. Id. sec. 3.

Sec. 2517.—Whoever unlawfully and intentionally injures or destroys or permits to be injured or destroyed any meter, pipe, conduit, wire, line, pole, lamp or other apparatus belonging to any person, firm or corporation engaged in the manufacture or sale of electricity for light, heat, power or other purpose, or unlawfully and intentionally prevents an electric meter from duly registering the quantity of electricity supplied, or in any way interferes with its proper action or just registration, or without the consent of such person, firm or corporation unlawfully and intentionally diverts any electric current from any wire of such persons, firm or corporation, or otherwise unlawfully and intentionally uses or causes to be used, without the consent of such person, firm or corporation, any electricity manufactured or distributed by such person, firm or corporation, shall be deemed guilty of a misdemeanor and shall for every such offense be punished by a fine not exceeding one hundred dollars, or imprisonment not exceeding one year, or by both fine and imprisonment. Act, March 29, 1923, p. 1015.

Carson vs. Fort Smith Light & Traction Co., 108 Ark. 452, dealt with the right of a consumer of gas upon placing money in a meter. The court said (pp. 456-457):

> In any event, it cannot be questioned that appellants had the right upon putting the quarter into the meter to consume the amount of gas for which it paid, and when it was so deposited and the gas turned into the meter, it was delivered to them and became their property with the right to consume it at their convenience, so long as the terms of the contract were not violated in so doing. Chouteau v. St. L. Gas Light Co., 47 No. Appeals, 326; Schmeer v. Gas Light Co., 147 N. Y. 529; 42 N. E. 202; 30 L. R. A. 653; Blondell v. Gas Co., 89 Md. 732; 43 Atl. 817; 46 L. R. A. 187.
>
> It may be true that the gas company had the right under its contract to shut off the supply of gas to appellants to compel the payments of amounts already due for gas consumed, or furnished, but it could not do so until after giving notice in accordance with the terms of the contract, and certainly with the slot meter in use and the money deposited therein for the payment of 1000 cu. ft. of gas according to the old price, and of that much upon the price of 1000 ft. according to the last rate fixed, it had no right to turn the gas already delivered to appellants out of the meter. If, according to the usage they are entitled to continue to consume 1000 ft. of gas for each quarter deposited in the meter until the meter could be changed to register in accordance with the advanced price, which we do not decide, the gas in the meter was already paid for, and if it can be said they should be held to the payment of the advance price for all the gas consumed since they were notified it should go into effect, then they would only have owed for the difference in the price, which would have been collected on the first of the succeeding month and could not have warranted their agent in turning the gas already delivered in the meter out. It

was as much a wrongful act as if he had taken or destroyed any other of the personal property or effects of these appellants in their homes.

It was a tort, pure and simple, committed without justification or excuse, and for which the gas company should be held answerable for all damages directly traceable to the wrong done and arising without an intervening agency and from no fault of the persons injured. Cov. v. Indianapolis Gas Co., 146 Ind. 665; 46 N. E. 17; 36 L. R. A. 535; Indiana Gas Co. v. Anthony, 26 Ind. App. 307; 58 N. E. 868; Thornton Oil & Gas, sec. 534.

California Penal Code 1923

Larceny

Sec. 498.—Every person who shall willfully, with intent to injure, or defraud, make or cause to be made, or uses or causes to be used, any pipe, tube or other instrument or conduit in connection with any main, service pipe or other pipe or conduit owned or controlled by any other person for conducting or supplying illuminating or fuel gas in such manner as to supply such or any illuminating or fuel gas to any burner, or outlet by or at which illuminating or fuel gas is consumed or otherwise used or wasted without passing through any meter provided for the measuring and registering the quantity of gas passing through such pipes, tubes or other conduits, or willfully acts in any other manner so as to evade, or cause the evasion of payment therefor, and every person who, with like intent, injures or alters any gas meter or register, or obstructs its action, is guilty of a misdemeanor. (Amendment approved 1909; Stats. 1909, p. 329.)

Sec. 499 a.—Every person who shall willfully and knowingly, with intent to injure or defraud, make or cause to be made any connection in any manner whatsoever with any electric wire or electric appliance of any character whatsoever operated by any person, persons or corporation authorized to generate, transmit and sell electric current, or who shall so willfully and knowingly with intent to injure or defraud, use or cause to be used any such connection in such manner as to supply any electric current for heat or light or power to any electric lamp, or apparatus or device, by or at which electric current for heat or light or power is consumed or otherwise used or wasted, without passing through a meter for the measuring and registering of the quantity passing through such electric wire or apparatus, or who shall knowingly and with like intent injure, alter or procure to be injured or altered any electric meter, or obstruct its working, or procure the same to be tampered with or injured, or use or cause to be used any electric meter, or appliance so tampered with or injured, shall be deemed guilty of a misdemeanor. (Amendment approved April 20, 1917; Stats. 1917, p. 150.)

Sec. 19.—Except in cases where a different punishment is prescribed by this code, every offense declared to be a misdemeanor is punishable by imprisonment in a county jail not exceeding six months, or by a fine not exceeding $500, or by both.

Colorado Compiled Laws 1921

Tapping Gas and Electrical Conduits

Sec. 6753.—Any person who connects any pipe, tube, stopcock or other instrument, device or contrivance with any main, service pipe or other pipe conducting or supplying, or intended to conduct or supply gas to any house, store or building, without the knowledge and consent of the person or corporation owning said pipe, in such manner that any portion of such gas may be conducted or supplied to any burner, orifice, heating apparatus or other instrument by or at which gas is consumed shall be deemed guilty of a misdemeanor and punished as provided in section five (5) hereof. (L. '09, p. 395, sec. 1.)

Sec. 6754.—Any person who connects any pipe, tube, stopcock or other instrument, device or contrivance with any main, service pipe or other pipe conducting or supplying or intended to conduct or supply gas to any house, store or other building without the knowledge and consent of the person or corporation owning said pipe, in such manner as to conduct or supply any such gas to any pipe, tube, burner, orifice, heating apparatus or other instrument by or at which gas is consumed, around or without passing through the meter provided for measuring or registering the amount or quantity of gas passing through it, shall be deemed guilty of a misdemeanor and punished as provided in section five (5) hereof. (L. '09, p. 395, sec. 2.)

Sec. 6755.—Any person who willfully injures, alters or by any instrument, device or contrivance in any manner interferes with or obstructs the action or operation of any meter made or provided for measuring or registering the amount or quantity of gas passing through it, without the knowledge and consent of the person or corporation owning said meter, shall be deemed guilty of a misdemeanor and punished as provided in section five (5) hereof. (L. '09, p. 396, sec. 3.)

Sec. 6756.—Proof of the existence of any pipe connection, or of any injury, alteration or obstruction of a meter, as in this act provided, shall be taken as prima facie evidence of the guilt of the person in possession of the premises where such connection, injury, alteration or obstruction is proved to exist. (L. '09, p. 396, sec. 4.)

Sec. 6757.—Any person convicted of a violation of any of the provisions of this act shall be punished for each offense by a fine of not less than fifty dollars ($50) nor more than three hundred dollars ($300), or by imprisonment in the county jail for a period of not less than thirty (30) days nor more than ninety (90) days, or both such fine and imprisonment. (L. '09, p. 396, sec. 5.)

Sec. 6758.—Any person who connects or changes any wire, cord, socket, motor or other instrument, device or contrivance, with any wire transmitting or supplying, or intended to transmit or supply electricity to any house, store or other building, without the knowledge and consent of the person or corporation owning said wire, in such manner that any portion of such electricity may be transmitted or supplied to any globe, lamp, heating apparatus or other instrument by or at which electricity is consumed, shall be deemed guilty of a misdemeanor and punished as provided in section five (5) hereof. (L. '09, p. 364, sec. 1.)

Sec. 6759.—Any person who connects or changes any wire, cord, socket, meter or other instrument, device or contrivance with any wire, transmitting or supplying or intended to transmit or supply electricity to any house, store or other building, without the knowledge and consent of the person or corporation owning said wire, in such manner as to transmit or supply any such electricity to any globe, lamp, heating apparatus or other instrument by or at which electricity is consumed, around or without passing through the meter provided for measuring or registering the amount or quantity of electricity passing through it, shall be deemed guilty of a misdemeanor and punished as provided in section five (5) hereof. (L. '09, p. 365, sec. 2.)

Sec. 6760.—Any person who willfully injures, alters or by any instrument, device or contrivance in any manner interferes with or obstructs the action or operation of any meter made or provided for measuring or registering the amount or quantity of electricity passing through it, without the knowledge and consent of the person or corporation owning said meter, shall be deemed guilty of a misdemeanor and punished as provided in section five (5) hereof. (L. '09, p. 365, sec. 3.)

Sec. 6761.—Proof of the existence of any wire connection, or of any injury, alteration or obstruction of a meter, as in this act provided, shall be taken as prima facie evidence of the guilt of the person in possession of the premises where such connection, injury, alteration or obstruction is proved to exist. (L. '09, p. 365, sec. 4.)

Sec. 6762.—Any person convicted of a violation of any of the provisions of this act shall be punished for each offense by a fine of not less than fifty dollars ($50) nor more than three hundred dollars ($300), or by imprisonment in the county jail for a period of not less than thirty (30) days nor more than ninety (90) days, or by both such fine and imprisonment. (L. '09, p. 365, sec. 5.)

Sec. 6763—Any person or persons who shall change, tap or connect with any electrical or gas apparatus, such as converters, meters, motors or other appliances, or with any electric light wire or gas pipe for the purpose of obtaining an electric current or gas for light, power or heat or for any other purpose whatever, without the knowledge and consent of the owner thereof or the person or persons or corporation, as the case may be, operating such apparatus, appliances, pipes and wires or who shall maliciously tamper with or injure any such apparatus, appliances, pipes or wires, shall be deemed guilty of a misdemeanor and, on conviction thereof, shall be punished for each offense by a fine of not less than fifty (50) dollars, nor more than three hundred (300) dollars or by imprisonment in the county jail for a period of not less than thirty (30) days nor more than ninety (90) days, or by both such fine and imprisonment. (L. '03, p. 115, sec. 1; R. S. '08, sec. 1880.)

Connecticut General Statutes 1918

Offenses Against Private Property

Sec. 6294.—Every person who shall, without permission, knowingly withdraw or cause to be withdrawn, and appropriate to himself for his own use or for the use of any other person, any current of electricity from the wires of any person or corporation authorized to manufacture, sell or use electricity for the purpose of light, heat or power; and any person having permission to use the said electric current for certain specified purposes who shall knowingly, willfully and intentionally withdraw or cause to be withdrawn such electric current for any other purpose; and every person to whom such electric current is furnished from or by means of a meter who shall willfully and with intent to cheat and defraud any of said persons or corporations, alter or interfere with such meter, or by any contrivance whatsoever withdraw or take off the electric current in any manner except through such meter, shall be fined not more than $50 or imprisoned not more than ninety days, or both.

Sec. 6296.—Every person who, with intent to defraud any person or corporation authorized to manufacture, sell or use gas for lighting, heating or power, shall connect any instrument or contrivance with any pipe for supplying gas, so as to effect the consumption thereof, without its passing through the meter provided for receiving and registering the quantity of gas passing through such pipe, or shall use or assist in connecting such meter; or who shall, without permission of the person or corporation supplying such gas knowingly use or waste any gas which has not passed through the meter provided for registering the consumption thereof, or has passed through such meter in such a manner as not to register the amount of gas so used or wasted; or who shall, by any means or device, knowingly take gas from the pipes of such person or corporation, with intent to evade payment therefor, or who shall, with like intent, make connection with such pipes for the purpose of taking such gas for his own use or for the use of another; or who shall take from any prepayment gas meter belonging to such persons or corporation any money or other valuable, or break or force open any such meter for the purpose of taking any money or valuable therefrom; or any agent of any manufacturer of such gas, who shall defraud another in quantity or quality, in the sale of such gas, in any manner, shall be fined not more than $50 or imprisoned in the county jail not more than ninety days, or both.

Delaware Revised Statutes 1915

Offenses Against Private Property

Sec. 4763.—It shall be unlawful for any person, without the consent of the owner thereof and with the intent not to pay for the same, to divert or cause to be diverted any electric current, while such current is being conveyed and transmitted through wires or conduits from the plant of the manufacturer of said electric current to the electric meter on the premises of any consumer thereof, or to cause any such electric current to be transferred from said wires or conduits to the premises of any consumer thereof without passing it through an electric meter on said premises provided by such manufacturer for the purpose of measuring the electric current furnished said premises, or, knowing such electric current to be so diverted to use it; every person violating any of the provisions of this section shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding $50 or by imprisonment not exceeding three months, or by both in the discretion of the court.

Sec. 4764.—It shall be unlawful for any person, without the consent of the owner thereof and with the intent not to pay for the same, to divert or cause to be diverted any illuminating gas, while such gas is being conveyed in pipes from the plant of the manufacturer of said gas to the gas meter on the premises of any consumer thereof, or to cause any such gas to be transferred from the said pipes to the premises of any consumer thereof without passing it through a gas meter on said premises provided by such manufacturer for the purposes of measuring the gas furnished said premises, or knowing such gas to be so diverted to use it; every person violating any of the provisions of this section shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding $50, or by imprisonment not exceeding three months, or by both in the discretion of the court.

District of Columbia Code of Law 1924

Offenses Against Property

Sec. 826a.—Whoever shall knowingly connect or disconnect any electrical conductor belonging to any company using or engaged in the manufacture and supply of electric current for purposes of light, heat and power, or either of them, or makes any connection with any such electrical conductor for the purpose of using or wasting the electric current, or who in any wise tampers with any meter used to register current consumed, or who interferes with the operating of any dynamo or other electrical appliance of such company, or tampers with or interferes with the poles, wires, conduits, or other apparatus used by such companies, unless such person or persons shall be duly authorized by or be in the employ of such company, shall be punished by a fine not exceeding $1,000, or imprisonment not exceeding one year, or both.

Florida Compiled General Laws 1927

Offenses Concerning Property

Sec. 7427.—Every person who shall willfully or fraudulently injure, or shall knowingly suffer to be injured any meter, wire, pipe or fittings connected with or belonging to an electric, gas or water plant owned or controlled by a person, firm or corporation, private or municipal, engaged in the business of furnishing electricity, gas or water to users thereof, or who shall willfully or fraudulently tamper or meddle with any meter or other appliance or plant in such manner as to cause loss or damage to the owner or operator of such plant, or shall willfully or fraudulently prevent any meter used for registering the same from registering the quantity so passing through the same, or shall alter the index or break the seal of any such meter or in any way hinder or interfere with its proper action of just registration, or shall fraudulently use or willfully waste or suffer the waste of electricity or gas or water passing through any such meter, wire, pipe or fitting, or other appliance or appurtenance connected with or belonging to any such plant after such meter, wire pipe fitting, appliance or appurtenance has been tampered with, injured or altered, shall be punished by fine not exceeding $500, or imprisoned not exceeding one year.

Sec. 7428.—Every person who, with intent to injure or defraud any person, firm or corporation, private or municipal, shall make or cause to be made any connection with any wire, main, service pipe or other pipe, appliance or appurtenance used for or in connection with an electric, gas or water plant, owned or controlled by any person, firm or corporation, private or municipal, engaged in the business of furnishing electricity, gas or water to users thereof, in such manner as to supply electricity, gas or water from such plant to any lamp, burner, orifice, faucet or other outlet whatsoever without such electricity, gas or water passing through a meter provided by the owner or manager of such plant and used for measuring and registering the quantity so passing through, or shall make or cause to be made, without the consent of the owner or operator of any such plant, any connection with any such plant, or any wire, main, pipe, service pipe, or other instrument or appliance connected with such plant, in such manner as to take, use or waste, without the consent of such owner or operator, any electricity, gas or water, or shall with intent to defraud the owner or operator of any such plant use any such electricity, gas or water so taken without the consent of such owner or operator shall be punished by a fine not exceeding $500 or by imprisonment not exceeding one year.

Georgia (Park's) Annotated Code of 1914 (Penal)

Interfering with Property of Electrical Companies

Sec. 783.—Whoever unlawfully and intentionally injures or destroys, or permits to be injured or destroyed, any meter, pipe, conduit, wire line, post, lamp, or other apparatus belonging to a company engaged in the manufacture or sale of electricity for lighting or power purposes, or unlawfully and intentionally prevents an electric meter from duly registering the quantity of electricity supplied, or in any way interferes with its proper action or just registration, or, without the consent of such company, unlawfully and intentionally diverts any electric current from any wire of such company, or otherwise unlawfully and intentionally uses or causes to be used, without the consent of such company, any electricity manufactured or distributed by such company, shall be punished as for a misdemeanor.

Sec. 1065.—Except where otherwise provided, every crime declared to be a misdemeanor is punishable by a fine not to exceed $1,000, imprisonment not to exceed six months, to work in the chain gang on the public roads, or on such other public works as the county or State authorities may employ the chain gang, not to exceed twelve months, any one or more of these punishments in the discretion of the judge; Provided, that nothing herein contained shall authorize the giving the control of convicts to private persons, or their employment by the county or State authorities in such mechanical pursuits as will bring the products of their labor into competition with the products of free labor. If the convict be a female, the judge may, in his discretion, sentence her to labor and confinement in the woman's prison on the State Farm, in lieu of a chain gang, sentence not to exceed twelve months: Provided, that the trial judge shall have the discretion also of sending any person convicted of a misdemeanor to the State Farm.

Sec. 230 (d). (Park's 1922 Supplement to Penal Code.)—Whoever unlawfully and intentionally injures or destroys, or permits to be injured or destroyed, any meter, pipe, conduit or other apparatus belonging to a company engaged in the manufacture or sale of gas for heating or lighting purposes, or unlawfully and intentionally prevents any gas meter from duly registering the quantity of gas supplied, or in any way interferes with its proper action or just registration or, without the consent of such company, unlawfully and intentionally diverts the flow of gas from any pipe of such company, or otherwise unlawfully or intentionally uses or causes to be used, without the consent of such company, any gas manufactured or distributed by such company, shall for every such offense be punished as provided in section 1065 of this code.

Idaho Compiled Statutes 1919

Larceny

Sec. 8447.—Whoever shall, without permission or authority of any person, firm or corporation engaged in the generation or distribution of electricity, make connections, or cause connections to be made, by wire or wires or by any other device, with the wires, cables or conductors, or any of them, of any such person, firm or corporation, for the purpose of obtaining or diverting electric current from such wires, cables or conductors, or whoever shall, without permission or authority from any person, firm or corporation using any meter or meters erected or set up for the purpose of registering or recording the amount of electric current supplied to any customer of such person, firm or corporation within this State, connect or cause to be connected by wire or any other device, any such meter or meters, or change or shunt the wiring leading to or from any such meter or meters, or by any device or appliance or means whatsoever tamper with any such meter or meters in such manner that such meter or meters do not measure or record the full amount of electric current supplied to such customer, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding $300, or by imprisonment in the county jail for a term not exceeding six months, or by both such fine and imprisonment; provided, that nothing herein contained shall be deemed to affect the right of any person, firm or corporation to recover by action in any court of competent jurisdiction damages for any injury done by such unlawful acts. ('05, p. 72, sec. 1.)

Sec. 8448.—Any person or persons aiding, abetting or counseling the acts, or any of them, mentioned in the preceding section, shall, upon conviction thereof, be equally guilty with the principals and subject to the same penalties. ('05, p. 72, sec. 2.)

Sec. 8449.—In all prosecutions under the two preceding sections, proof that any of the acts herein forbidden were done on or about the premises owned or occupied by the defendant charged with the commission of such offense, or that he received the benefit of any such electric current on account of the commission of such acts, shall be prima facie evidence of the guilt of such defendant. ('05, p. 72, sec. 3.)

Ch.208, Idaho Session Laws 1921

Sec. 1.—Any person who, with intent to injure or defraud any company, corporation, copartnership or individual, authorized to manufacture, generate, sell or use illuminating or inflammable gas for lighting, heating or power purposes, shall injure, alter, obstruct or prevent the action of any meter, provided for the purpose of measuring the quantity of gas consumed by, or at, any burner, orifice or place, or supplied to any lamp, stove, range, furnace, machine, motor, appliance or contrivance, or who shall cause, or procure, or aid, the injuring or altering of any such meter or the obstruction or prevention of its action, or who shall make or cause to be made, with any pipe, tube or any appliance, any connection, so as to conduct or supply illuminating or inflammable gas to any burner, or orifice, or lamp, or stove, or range, or furnace, or motor, or other machine or appliance from which such gas may be consumed or utilized without passing through, or being registered by such meter, without the permission, consent or acquiescence of the company, corporation, copartnership, or individual, furnishing or transmitting such gas, or who shall knowingly use or utilize any such gas which has not passed through the meter provided for the registration of the consumption thereof, or who shall by any means, device, appliance or contrivance, knowingly use or utilize such gas for his own use, or for the use of another, with intent to evade payment thereof, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding three hundred dollars ($300), or by imprisonment in the county jail for a term not exceeding six months, or by both such fine and imprisonment.

Sec. 2.—Any such company, corporation, copartnership or individual, authorized to manufacture, generate, sell or use illuminating or inflammable gas, who shall have probable cause to believe that any person, firm, company, copartnership or corporation is violating the provisions of this act, shall, upon making the affidavit required in, and complying with all the provisions of Chapter 332, of Title 61, of the Compiled Statutes, be entitled to have a search warrant issued to it and served in the manner provided in said Chapter 332, of Title 61.

Sec. 3.—Nothing herein contained shall be deemed to affect the right of any company, corporation, copartnership, firm or individual, to recover by civil action, in any court of competent jurisdiction, the reasonable value of such gas used, or damages for any injury done by such unlawful acts.

Illinois (Cahill) Revised Statutes 1927

Chapter 38—Criminal Code

Par. 279.—Any person who, with intent to injure or defraud any company, body corporate, copartnership or individual, shall injure, alter, obstruct or prevent the action of any meter provided for the purpose of measuring and registering the quantity of gas, water or electric current consumed by or at any burner, orifice or place, or supplied to any lamp, motor, machine or appliance, or shall cause or produce or aid the injuring or altering of any such meter, or the obstruction or prevention of its action, or shall make or cause to be made with any gas pipe, water pipe or electrical conductor any connection so as to conduct or supply illumination or inflammable gas, water, or electric current to any burner or orifice, or lamp, or motor, or other machine or appliance from which such gas, water or electricity may be consumed or utilized without passing through or being registered by a meter or without the consent or acquiescence of the company, municipal corporation, body corporate, copartnership or individual furnishing or transmitting such gas, water or electric current through such gas pipe, water pipe or electrical conductor shall be punished by imprisonment not exceeding three (3) months, or a fine not exceeding two hundred and fifty dollars ($250), or both. (J. & A., par. 3698.)

In Woods vs. The People, 222 Ill. 293, 298, James Woods and Thomas Light were indicted for the crime of larceny, namely, the larceny of illuminating and natural gas from the Peoples Gas, Light & Coke Company. On the trial, Light was acquitted and Woods was convicted, the property taken having been found by the jury to exceed $15 in value, and he was sentenced to the penitentiary for an indeterminate period. Woods prosecuted a writ of error from the Supreme Court to reverse said judgment.

It appears from the evidence that the plaintiff in error was a dancing master, and from March, 1903, to December, 1904, conducted a dancing academy in a building located at 3947 Michigan Avenue, in the city of Chicago, which building was to be lighted and heated by gas furnished through meters located in said building under and by virtue of a contract between the plaintiff in error and said light and coke company; that at regular intervals during said period the plaintiff in error or his employees removed the meters and by rubber hose connections caused the gas to pass from the gas service pipes of said light and coke company in said building direct to the gas burners in said building, where it was ignited and burned by the plaintiff in error for illuminating and heating purposes without being registered, his scheme being to remove the meters and substitute the rubber hose connections each month immediately after the meter reader had visited said premises and read the meters, and to allow said rubber hose connections to remain in place for about twenty days, or until about ten days before the reader of meters would return to said building, when he would replace the meters and allow them to remain in position until the meter reader had read them, when he would again remove said meters and substitute the rubber hose connections therefor; that sometime prior to the 14th day of December, 1904, he substituted for the rubber hose connections a system of pipes which were concealed in the walls of the building and which connected the gas burners within the building with the regular service pipes of said light and coke company which entered said building, and which concealed pipes were fitted with a stopcock, which, when turned, prevented the gas flowing through the meters and caused the same to flow direct to the gas burner, where it was ignited and used for illuminating and heating purposes in said building. The larceny of plaintiff in error was discovered by the inspectors of the light and coke company on the evening of Dec. 14, 1904, at which time gas was passing through the concealed pipes in the wall to the burners in the building and being consumed in large quantities for illuminating and heating purposes without being registered. The plaintiff in error at that time admitted gas had been passing through said concealed pipes for three or four days prior to Dec. 14, and the evidence shows that the plaintiff in error had used gas for lighting and heating purposes in said building, admitted through the said rubber hose and without the same passing through the meters and being registered, for stated periods of about twenty days in each month from April, 1903, to December, 1904. There is, therefore, no question but that the plaintiff in error was properly convicted, if the taking of gas in the manner above described constitutes the crime of larceny and no reversible error was committed on the trial.

In affirming the judgment of the lower court, the Supreme Court said:

> The first contention made by plaintiff in error is, that the offense made out against him by the evidence falls within the special statutory crime created by section 117 of the Criminal Code (1 Starr & Cur. Stat.—2nd ed.—par. 234, chap. 58, p. 1288), and not under section 167 of the Criminal Code, which defines the crime of larceny, and that he should have been prosecuted for a violation of said section 117, and not for the crime of larceny. We do not agree with such contention. The law is well settled that gas used for illuminating and heating purposes may be the subject of larceny. (Commonwealth vs. Shaw, 4 Allen, 308; State vs. Wellman, 34 Minn. 221; Regina vs. White, 6 Cox C. C. 213.)
>
> Section 117 of the statute above referred to does not undertake to punish a person who unlawfully abstracts gas from the pipes of a gas company, but that section of the statute was passed with a view to protect gas, water or electric meters from being tampered with or false connections being made with gas or water pipes or electrical conductors, so that gas, water or electricity might be consumed or utilized without passing through or being registered by a meter. The crime of larceny and the crime created by that section of the statute are therefore entirely separate and distinct offences, and the doctrine announced in Stoker vs. People, 114, Ill. 320, and kindred cases, relied upon by plaintiff in error, has no application to the case at bar. The plaintiff in error might have been guilty of a violation of said section 117 without obtaining any gas from said light and coke company. The two offences are not the same,

and the evidence which would support a conviction for a violation of same section 117 of the statute would not necessarily even tend to show the plaintiff in error guilty of larceny. The trial court did not, therefore, err in holding that the plaintiff in error was not entitled to his discharge on the ground that he was being prosecuted for the wrong offence.

It is next contended that, conceding the plaintiff in error was guilty of larceny, the evidence does not show him to be guilty of grand larceny, as it is said there is no evidence in the record that the value of the gas converted by him to his own use at any one time exceeded in value the sum of $15. The correctness of this contention depends upon whether the evidence shows the plaintiff in error to have been guilty of a continuing offence. If the gas abstracted on each day is a single and complete offence then the contention of the plaintiff in error would be correct, as the evidence failed to show that more than $15 worth of gas was consumed at 3947 Michigan Avenue during any one day while the plaintiff in error was in possession of said premises. On the contrary, however, if it be the law that all the gas which was consumed by the plaintiff in error during any one period while the service pipes of said light and coke company were connected with the burners in said building by said rubber hose or the concealed pipes should be treated as one continuous taking, then clearly the evidence shows the plaintiff in error to have been guilty of grand larceny. In Bishop on Criminal Law (vol. 2—7th ed.—p. 799) it is said: "Illuminating gas may be the subject of larceny; and the asportation is sufficient where the prisoner, receiving gas of a gas company, diverts some of it to his burners without its passing the meter to be measured, the means employed being to use a pipe running directly from the entrance to the exit pipe. While the pipe remains thus connected there is held to be one continuous taking."

It is finally contended that the court erred in directing the jury that in fixing the value of the gas stolen, if any, they should be guided by the selling price of the gas in question to consumers in the district in which the gas was abstracted, and not by the cost value of the material from which the gas was made. We are of the opinion the court did not err in so instructing the jury. The ordinary test of the value of property is the price it will command in the market if offered for sale, which in this case was the selling price of gas to consumers in the vicinity where the plaintiff in error wrongfully converted the gas of the light and coke company to his own use.

Indiana (Burns') Annotated Statutes 1926

Offenses Against Property

Sec. 2509.—Whoever, unlawfully and intentionally, injures or destroys, or permits to be injured or destroyed, any meter, pipe, conduit, wire, line, post, lamp or other apparatus belonging to a company engaged in the manufacture or sale of electricity for light, heat, power or other purposes; or whoever, unlawfully and intentionally, prevents an electric meter from duly registering the quantity of electricity supplied, or in any way interferes with its proper action or just registration; or whoever, without the consent of such company, unlawfully and intentionally diverts any electric current from any wire of such company, or otherwise unlawfully and intentionally uses or causes to be used, without the consent of such company, any electricity manufactured or distributed by such company, shall be deemed guilty of a misdemeanor, and, on conviction, shall, for every such offence, be punished by a fine not exceeding $100, or by imprisonment in the county jail not exceeding one year, or by both such fine and imprisonment.

Offenses Against Honest Dealing

Sec. 2971.—Whoever knowingly constructs, or uses or furnishes to gas consumers to be used, any false meter provided for measuring and registering the quantity of gas consumed by any person under a contract with any gas company, shall, on conviction, be fined not less than $10, nor more than $100.

Miscellaneous Offenses

Sec. 3011.—It is hereby declared to be unlawful for any person, in any manner whatever, to change, extend or alter, or cause to be changed, extended or altered, any service or other pipe or attachment of any kind connecting or through which natural or artificial gas is furnished from the gas mains or pipes of any person, company or corporation without first procuring from said person, company or corporation written permission to make such change, extension or alteration.

Sec. 3012.—It is hereby declared to be unlawful for any person to make, or cause to be made, any connection or reconnection, with the gas mains or service pipes of any person, company, or corporation, furnishing to consumers natural or artificial gas, or to turn on or off, or in any manner interfere with, any valve or stopcock, or other appliances belonging to such person, company or corporation, and connected with its service or other pipes, or to enlarge the orifice of mixers, or to use natural gas for heating purposes except through mixers, without first procuring from such person, company or corporation a written permit to turn on or off such stopcock or valve, or to make such connections or reconnection, or to enlarge the orifice of mixers, or to use gas for heating without mixers, or to interfere with the valves, stopcocks, or other appliances of such person, company or corporation, as the case may be.

Sec. 3015.—Any person violating any provision of this act shall, upon conviction, be fined in any sum not less than $5 nor more than $100 for such offence.

In State vs. Moore, 27 Ind. App. 83, 86-87, the defendant was prosecuted under Sections 2705 and 2706 of the Indiana laws, supra, on the charge of interfering with natural gas connections without first having procured a written permit to do so. He was acquitted, and the State appealed. In sustaining the appeal, the court said:

> The court instructed the jury that the defendant should not be convicted unless the jury believed that, in doing the acts charged, he acted with an evil intent, or intended to perform a wrongful act. And also that if the defendant executed to a company a gas and oil lease on his farm, and the company thereafter constructed a well thereon which produced gas in large quantities, and piped the gas therefrom to consumers without right to do so and in violation of the contract, and used gas for no other purpose, and was so using it at the time of the offence, the defendant had the legal right to turn off the gas from the line and prevent the wrongful use thereof by the company.
>
> The maxim, "Actus non facit reum, nisi mens sit rea," cannot have a like application in all cases. It must be given a meaning with reference to the particular definitions of the crimes. The mens rea in manslaughter means a guilty mind, but it would be contradictory to say these words mean a guilty mind in a case of manslaughter by negligence—to say that the mere absence of mind is a guilty mind. It is evident the maxim cannot have a universal application, and that an act may be a crime without the element of intent.
>
> It is a matter of common knowledge that natural gas is a dangerous agency, and of that fact courts take judicial notice. As such agency it is clear that its use may be made the subject of police regulation. The legislature, in the act in question, concluded, as it had the power to do, that the public safety and welfare required that the use of natural gas is a subject properly within legislative control. The act charged is not made a crime because of its moral turpitude or the criminal intent with which it was committed, but it is a prohibited act from motives of public policy. The statute makes the act charged unlawful. The doing of the act is a misdemeanor. The question is not whether he intended to perform a wrongful act. If he did the act without having the written permit, he violated the statute regardless of whether or not it was done with evil intent. If the agreement or lease introduced in evidence contained anything that might be construed as a

permit to appellee to interfere with the main under certain conditions, a different question would be presented. But the lease contains no such stipulation, nor anything that might be construed as such. If appellee had a contract that was being violated, a court would have granted relief. Appellee was charged with the voluntary commission of an act prohibited by a statute passed to subserve a public policy, and the voluntary doing of the act, regardless of his intent, constitutes the offence; State vs. Engle, 156 Ind. 339, and cases cited; Commonwealth vs. Raymond, 97 Mass. 567; State vs. Hartiel, 24 Wis. 60; Eagle vs. Nowline, 94 Fed. 646, See Barton vs. State, 99 Ind. 89; Tilford vs. State, 109 Ind. 359; Edwards vs. State, 121 Ind. 450.

The appeal is sustained.

In Gary Heat, Light & Water Co. vs. George Christ et al., P. U. R. 1921 C. 355, 358-359, the Indiana Public Service Commission said:

It would be an unjust discrimination to permit individual consumers, who have made separate contracts for service, to rearrange the service pipes so that two or more could receive gas through one meter.

The shifting of the meters in the manner disclosed by the evidence is a misdemeanor, which, under the statutes of Indiana, is punishable by a fine of not less than $5 nor more than $100. It is unlawful for any person, in any manner whatsoever to change, extend or alter, or cause to be changed, extended or altered any service or other pipe or attachment of any kind connecting or through which natural gas or artificial gas is furnished from the gas mains or pipes of any person, company or corporation, without first procuring from said person, firm, company or corporation written permission to make such change, extension or alteration. B. R. S. 1914, Sec. 2705.

The running of a service pipe from the premises of Christ to the premises of Apostoles Brothers, without the consent or authority of petitioner, in the manner disclosed by the evidence, is also a misdemeanor with the same penalty attaching. It is unlawful for any person to make, or cause to be made, any connection or reconnection, with the gas mains or service pipes of any person, company or corporation, furnishing to consumers natural or artificial gas, or to turn on or off, or in any manner interfere with any valve or stopcock, or other appliances belonging to such person, company or corporation, and connected with its service or other pipes, or to enlarge the orifice of mixers, or to use natural gas for heating purposes except through mixers, without first procuring from such person, company or corporation a written permit to turn on or off such stopcock or valve, or to make such connection or reconnection, or to enlarge the orifice of mixers, or to use gas for heating without mixers, or to interfere with the valves, stopcocks or other appliances of such person, company or corporation, as the case may be. B. R. S. 1914, Sec. 2706.

The prosecution of any person for a violation of either of the two above mentioned statutes is, of course, entirely beyond the jurisdiction of the commission.

Iowa Code 1927

Larceny

Sec. 13014.—If any person wilfully, and with intent to defraud, in any manner takes from the wires, pipes, meters, or any other apparatus of any electric motor, electric light, water, steam heating, or gas plant or works, any electric current, water, steam, steam heat, or gas, he shall be guilty of larceny and shall be punished accordingly.

Sec. 13006.—When the value of the property stolen exceeds $20, he shall be punished by imprisonment in the penitentiary not more than five years, or in the county jail not more than one year, or by fine of not more than $1,000, or by both such fine and imprisonment; when the value does not exceed $20, by fine not exceeding $100, or imprisonment in the county jail not exceeding thirty days.

Injuries to Internal Improvements and Common Carriers

Sec. 13120.—If any person maliciously injure, remove or destroy any electric railway or apparatus belonging thereto, or any bridge, rail or plank road; or place or cause to be placed, any obstruction on any electric railway, or on any such bridge, rail or plank road; or willfully obstruct or injure any public road or highway; or maliciously cut, burn, or in any way break down, injure or destroy any post or pole used in connection with any system of electric lighting, electric railway, or telephone or telegraph system or break down and destroy or injure and deface any electric light, telegraph or telephone instrument; or in any way cut, break or injure the wires of any apparatus belonging thereto; or shall willfully tap, cut, injure, break, disconnect, connect, make any connection with, or destroy any of the wires, mains, pipes, conduits, meters, or other apparatus belonging to, or attached to, the power plant or distributing system of any electric light plant, electric motor, gas plant or water plant; or shall aid or abet any other person in so doing, he shall be imprisoned in the penitentiary not more than five years, or be fined not exceeding $500, or imprisoned in the county jail not more than one year, or by both such fine and imprisonment, at the discretion of the court.

Kansas Revised Statutes Annotated 1923

Telegraph, Telephone and Transmission Lines

Sec. 17-1908.—Any person who shall unlawfully and willfully cut, break, tap or make connection with any telegraph, telephone line or electric transmission line, wire or cable, shall be deemed guilty of a misdemeanor, and be punished by a fine not exceeding $500, or by imprisonment in the county jail not exceeding one year, or by both such fine and imprisonment. (L. 1921, Ch. 151, Sec. 2; May 25.)

Oil and Gas

Sec. 55-107.—That it shall be unlawful for any person to make or cause to be made any connection or reconnection with the gas mains or surface pipes of any person, company or corporation furnishing natural gas, or to turn on or off or in any manner interfere with any valve, stopcock or other appliance belonging to such person, company or corporation and connected with its surface or other pipes, or to alter or injure the orifice of mixers, or to use natural gas for heating purposes except through mixers, without first procuring from such person, company or corporation a written permit to turn on or off such stopcock or valve, or to make such connections or reconnections, or to alter or injure the orifice of mixers, or to interfere with the valves, stopcocks or other appliances of such person, company or corporation, as the case may be. (L. 1901, Ch. 224, Sec. 5; March 22.)

Sec. 55-109.—Any person violating any of the provisions of Sec. 5, 6 and 7 of this act shall be deemed guilty of a misdemeanor, and upon conviction shall be fined not less than $25 nor more than $100, and shall be liable to the said person, company or corporation whose property was so changed, injured, altered or destroyed, in a civil action for the amount of damages sustained, together with all the costs in the case. (L. 1901, Ch. 224, Sec. 8; March 22.)

Kentucky (Carroll's) Statutes 1922

Offenses Against Property

Sec. 1262a-1.—That any person who, without the consent of any person, firm, co-partnership or corporation engaged in the manufacture or distribution of electricity, shall unlawfully convert to his own use, from any wire of such person, firm, co-partnership or corporation any portion of such electric current or electricity, or who shall prevent such current, or any part thereof, from passing through any meter provided for measuring it by such person, firm. co-partnership or corporation, or who shall, in any manner prevent such meter from correctly registering the current passing through it, or shall aid, in any manner, in the unlawful conversion to his use or the use of another, of any portion of such electric current, shall be fined not less than $50 nor more than $500, or imprisoned not less than three months nor exceeding twelve months, or both so fined and imprisoned, in the discretion of the jury trying the case.

Sec. 1262a-2.—Any person who shall unlawfully and maliciously destroy, injure or otherwise interfere with any meter, pipe, conduit, wire, line, pole, lamp or other apparatus belonging to any person, firm, co-partnership, or corporation engaged in manufacturing and selling electricity, shall be punished by a fine of not less than $5 nor more than $500, or imprisoned not less than ten days nor more than one year, or both so fined and imprisoned, in the discretion of the jury.

Sec. 1262a-3.—Any person who shall have in his possession any machine, appliances or contrivance of any character, used or intended to be used to prevent a meter from correctly registering the electric current passing through such meter or for diverting the electric current that should pass through such meter, shall be punished by a fine of not less than $50 nor more than $500, or imprisoned not less than three months nor more than twelve months, or both so fined and imprisoned, in the discretion of the jury.

Sec. 1262a-4.—Anyone who shall knowingly accept and receive the use and benefit of a current of electricity diverted as provided for in Sec. 3 hereof, shall be guilty of a misdemeanor; and upon conviction shall be fined not less than $50 nor more than $500, or imprisoned in the county jail for not less than three months nor more than one year, or both so fined and imprisoned, in the discretion of the jury.

Sec. 1262a-5.—Any indictment shall be valid which charges any or all of the acts denounced in Sec. 1, 2, 3 and 4 hereof in one count, and all of said acts may be charged and embraced in a single count in an indictment. (This section is an act of March 22, 1902; the numbers of the sub-sections are the numbers of the act.)

Acts of the Legislature of the State of Louisiana for the Year of 1926

Damaging, Injuring, Defacing or Defrauding, Etc., of Gas and Electric Meters

Act. No. 116.—Making it unlawful to obtain for use, or to attempt to obtain for use, or to aid or to assist anyone in obtaining for use, or in attempting to obtain for use, electricity manufactured and held for sale or distribution, by persons, firms or corporations engaged in the manufacture, sale or distribution of electricity, without the consent of, and with intent to defraud such persons, firms or corporations, through the means and devices of diverting from the wires or cables of such persons, firms or corporations electricity manufactured, held for sale or distribution by such persons, firms, or corporations; or preventing the electric meter or meters furnished by such persons, firms or corporations from registering the quantity of electric current passing through such meter or meters, or from registering the correct amount of electricity used; of interfering with the proper action of just registration of such electric meter or meters; of preventing electric current from passing through such meter or meters; defining what shall be prima facie evidence of the provisions thereof; making the violations of the provisions of this act a misdemeanor and providing penalties therefor.

Sec. 1.—Be it enacted by the Legislature of Louisiana, That if any person or persons obtains for use and whoever aids or assists such person or persons in obtaining for use electricity manufactured, or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of electricity with the intent to defraud them and without the consent of such persons, firms or corporations, by diverting the said electricity, by any means or device or devices, from the wires or cables of such persons, firms or corporations, the said person or persons so obtaining such electricity for use and anyone aiding or assisting in so obtaining for use such electricity, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by imprisonment in the Parish Prison for not less than thirty days nor more than six months.

Sec. 2.—That if any person or persons attempts to obtain for use, and whoever aids or assists such person or persons in attempting to obtain for use electricity manufactured, held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of electricity, without the consent of such persons, firms or corporations, and with intent to defraud such persons, firms and corporations by any means, or by any device or devices by which electricity is diverted from the wires or cables of such persons, firms or corporations, the said person or persons so attempting to obtain for use such electricity, and all those aiding or assisting therein, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by imprisonment in the Parish Prison for not less than ten days nor more than thirty days.

Sec. 3.—That if any person or persons obtains for use and whoever aids or assists such person or persons in obtaining for use electricity manufactured, or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of electricity, without the consent of such persons, firms or corporations, and with the intent to defraud such persons, firms or corporations, through or by means of any device or devices that prevent electric current belonging to such persons, firms or corporations from passing through any meter or meters belonging to such persons, firms or corporations, and furnished to register the quantity of current of electricity passing through such meter or meters, or the amount used, such person or persons so obtaining for use such electricity, and anyone aiding and assisting therein, shall be guilty of a misdemeanor and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 4.—That if any person or persons obtains for use and whosoever aids or assists such person or persons in obtaining for use electricity manufactured by or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of electricity without the consent of such persons, firms or corporations and with intent to defraud them, by or through any means or device that interferes with the proper action or just registration of any meter or meters belonging to such persons, firms or corporations and furnished to register the current of electricity passing through such meter or meters or the amount used, such person or persons shall be deemed guilty of a misdemeanor and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 5.—That if any person or persons attempts to obtain for use, and whoever aids or assists such person or persons in attempting to obtain for use electricity manufactured or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of electricity without the consent of such persons, firms or corporations and with the intent to defraud such persons, firms or corporations, through or by means of any device or devices that prevent electric current belonging to such persons, firms or corporations from passing through any meter or meters belonging to such persons, firms or corporations, and furnished to register the quantity of current of electricity passing through such meter or meters, or the amount used, such person or persons so attempting to obtain for use such electricity, and anyone aiding and assisting therein, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 6.—That if any person or persons attempting to obtain for use, and whoever aids or assists any person or persons in attempting to obtain for use electricity manufactured or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of electricity without the consent of such persons, firms or corporations and with intent to defraud them, by or through any means or device that interferes with the proper action or just registration of any meter or meters belonging to such persons, firms or corporations and furnished to register the current of electricity passing through such meter or meters or the amount used, such person or persons and anyone aiding or assisting them, shall be deemed guilty of a misdemeanor and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 7.—That the presence at any time on or about such meter or meters, on or about such wire or cables, of any device or wire resulting in the diversion of electric current, or resulting in the prevention of the proper action of just registration of the meter or meters, as above set forth, or preventing the meter or meters from registering, shall constitute prima facie evidence of knowledge on behalf of the person or persons having custody or control of the place or room where such device or wire is located, of the existence thereof and the effect thereof, and shall constitute prima facie evidence of the intention of such person or persons to defraud and acting with consent and shall bring such person or persons prima facie within the scope, meaning and penalties of this Act.

Sec. 8.—That, if any clause, sentence, paragraph, or part of this act shall for any reason be adjudged by any court of competent jurisdiction to be invalid, such judgment shall not affect, impair or invalidate the remainder of this act, but shall be confined in its operation to the clause, sentence, paragraph, or any part thereof, directly involved in the controversy in which such judgment has been rendered.

Act No. 117.—Making it unlawful to obtain for use, or to attempt to obtain for use, or to aid or to assist anyone in obtaining for use gas manufactured, held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale, or distribution of gas without the consent of, and with intent to defraud such persons, firms or corporations, through the means and devices of diverting from the pipes or mains of such persons, firms or corporations gas manufactured, held for sale or distribution by such persons, firms or corporations; of preventing the gas meter or meters furnished by such persons, firms or corporations from registering the quantity of gas passing through such meter or meters, or from registering the correct amount of gas used; of interfering with the proper action of just registration of such gas meter or meters; or preventing gas from passing through such meter or meters; defining what shall be prima facie evidence of the provisions thereof; making the violations of the provisions of this act a misdemeanor and providing penalties therefor.

Sec. 1.—Be it enacted by the Legislature of Louisiana, That if any person or persons obtains for use and whoever aids or assists such person or persons in obtaining for use gas manufactured, or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of gas, with the intent to defraud them and without the consent of such persons, firms or corporations, by diverting the said gas, by any means or device or devices, from the pipes or mains of such persons, firms or corporations, the said person or persons so obtaining such gas for use and anyone aiding or assisting in so obtaining for use such gas, shall be deemed guilty of a misdemeanor and upon conviction shall be punished by imprisonment in the Parish Prison for not less than thirty days nor more than six months.

Sec. 2.—That if any person or persons attempts to obtain for use and whoever aids or assists such person or persons in attempting to obtain for use gas manufactured, held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of gas, without the consent of such persons, firms or corporations and with intent to defraud such persons, firms and corporations by any means, or by any device or devices, by which gas is diverted or could be diverted from the pipes or mains of such persons, firms or corporations the said person or persons so attempting to obtain for use such gas and all those aiding or assisting therein, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by imprisonment in the Parish Prison for not less than ten days nor more than thirty days.

Sec. 3.—That if any person or persons obtains for use and whoever aids or assists such person or persons in obtaining for use gas manufactured, or held for sale or distribution by persons, firms, or corporations, engaged in the manufacture, sale or distribution of gas, without the consent of such persons, firms or corporations and with the intent to defraud such persons, firms or corporations through or by means of any device or devices that prevents gas belonging to such persons, firms or corporations from passing through any meter or meters belonging to such persons, firms or corporations, and furnished to register the quantity of gas passing through such meter or meters, or the amount used, such person or persons so obtaining for use gas and anyone aiding and assisting therein shall be deemed guilty of a misdemeanor and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 4.—That if any person or persons obtains for use and whoever aids or assists such person or persons in obtaining for use gas manufactured by or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of gas without the consent of such persons, firms or corporations and with intent to defraud them, by or through any means or device that interferes with the proper action or just registration of any meter or meters belonging to such persons, firms or corporations and furnished to register, the gas passing through such meter or meters or the amount used, such person or persons shall be deemed guilty of a misdemeanor and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 5.—That if any person or persons attempts to obtain for use and whoever aids or assists such person or persons in attempting to obtain for use gas manufactured or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of gas without the consent of such persons, firms or corporations and with the intent to defraud such persons, firms or corporations, through or by means of any device or devices that prevents gas belonging to such persons, firms or corporations from passing through any meter or meters belonging to such persons, firms or corporations and furnished to register the quantity of gas passing through such meter or meters, or the amount used, such person or persons so attempting to obtain for use such gas and anyone aiding and assisting therein shall be deemed guilty of a misdemeanor and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 6.—That if any person or persons attempts to obtain for use and whoever aids or assists such person or persons in attempting to obtain for use gas manufactured by or held for sale or distribution by persons, firms or corporations engaged in the manufacture, sale or distribution of gas without the consent of such persons, firms or corporations and with intent to defraud them, by or through any means or device that interferes with the proper action or just registration of any meter or meters belonging to such persons, firms or corporations and furnished to register the gas passing through such meter or meters or the amount used, such person or persons and anyone aiding or assisting them shall be deemed guilty of a misdemeanor and upon conviction shall be punished by imprisonment of not less than ten days nor more than thirty days in the Parish Prison.

Sec. 7.—That the presence at any time on or about such meter or meters, on or about such pipes or mains or any device or wire resulting in the diversion of gas, or resulting in the prevention of the proper action or just registration of the meter or meters as above set forth or preventing the meter or meters from registering shall constitute prima facie evidence of knowledge on behalf of the person or persons having custody or control of the place or room where such device or wire is located, of the existence thereof and the effect thereof and shall constitute prima facie evidence of the intention of such person or persons to defraud and acting without consent, and shall bring such person or persons prima facie within the scope, meaning and penalties of this Act.

Sec. 8.—That, if any clause, sentence, paragraph, or part of this act shall for any reason be adjudged by any court of competent jurisdiction to be invalid, such judgment shall not affect, impair, or invalidate the remainder of this act, but shall be confined in its operation to the clause, sentence, paragraph, or any part thereof, directly involved in the controversy in which such judgment has been rendered.

Act No. 118.—Making it unlawful to willfully or intentionally injure or deface any electric meter; or any electric meter inclosing device; or any seals placed upon any electric meter or electric meter inclosing device; defining the terms "electric meter," and "electric meter inclosing device"; making any violation of the provisions of this act a misdemeanor and providing penalties therefor.

Sec. 1.—Be it enacted by the Legislature of Louisiana, That whoever shall willfully or intentionally injure or deface any electric meter, or any electric meter inclosing device, or any seals placed upon any electric meter or electric meter inclosing device, shall be deemed guilty of a misdmeanor and upon conviction shall be punished by a fine of not less than $10 nor more than $100, or by imprisonment for not less than ten days nor more than ninety days, or both.

Sec. 2.—The term "electric meter" as used in this act shall mean any instrument, contrivance, apparatus or machine belonging to any person, firm or corporation, engaged in the manufacturing, sale or distribution of electricity and furnished to register the quantity of electricity used by the user or consumer thereof. The term "electric meter inclosing device" as used in this act shall mean any instrument, contrivance or apparatus within which such electric meter may be placed or housed.

Act 119.—Making it unlawful to willfully or intentionally injure, or deface any gas meter, or any gas meter inclosing device; or any seals placed upon any gas meter or gas meter inclosing device. Defining the terms "gas meter," and "gas meter inclosing device"; making any violation of the provision of this act a misdemeanor and providing penalties therefor.

Sec. 1.—Be it enacted by the Legislature of Louisiana, That whoever shall willfully or intentionally injure or deface any gas meter, or any gas meter inclosing device, or any seals placed upon any gas meter or gas meter inclosing device, shall be deemed guilty of a misdemeanor and upon conviction shall be punished by a fine of not less than $10 nor more than $100, or by imprisonment for not less than ten days nor more than ninety days, or both.

Sec. 2.—The term "gas meter" as used in this act shall mean any instrument, contrivance, apparatus or machine belonging to any person, firm or corporation, engaged in the manufacturing, sale or distribution of gas and furnished to register the quantity of gas used by the user or consumer thereof. The term "gas meter inclosing device" as used in this act shall mean any instrument, contrivance or apparatus within which such gas meter may be placed or housed.

Maine Revised Statutes 1916

Chapter 129—Malicious Mischiefs and Trespasses

Sec. 11.—Whoever unlawfully and intentionally injures or destroys or suffers to be injured or destroyed any meter, pipe, conduit, wire, line, pole, lamp or other apparatus belonging to an individual, co-partnership or corporation engaged in the manufacture or sale of gas or electricity for lighting purposes or power purposes, or belonging to any water company, or unlawfully and intentionally prevents an electric, water or gas meter from duly registering the quantity of electricity, water or gas supplied, or in any way interferes with its proper action or just registration, or without the consent of such individual, co-partnership or corporation unlawfully and intentionally diverts any electric current from any wire of such individual, co-partnership or corporation, or otherwise unlawfully and intentionally uses or causes to be used without the consent of such individual, co-partnership or corporation any electricity manufactured or distributed by such individual, co-partnership or corporation, or unlawfully and intentionally and without the consent of such company taps, or interferes with the pipes or fixtures of any gas company, shall for every such offence be punished by a fine of not more than one hundred dollars, or by imprisonment for not more than one year, or by both such fine and imprisonment.

Maryland (Bagby) Annotated Code 1924

Article 27—Fraud—Upon Gas Companies

Sec. 179.—Any person who, with intent to injure or defraud any gas company, body corporate of this State, shall make, or cause to be made, any pipe, tube or other instrument or contrivance, or connect the same, or cause it to be connected, with any main service pipe or other pipe for conducting or supplying gas, in such manner as to connect with and be calculated to supply gas to any burner or orifice, by or at which gas is consumed, around or without passing through the meter provided for the measuring and registering of the quantity of gas there consumed, shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be punished by imprisonment not exceeding six months, or by fine not exceeding $250, or both, in the discretion of the court. The existence of any pipe or tube connection or other instrument or contrivance, as aforesaid, permitting the use of gas furnished by any gas company, body corporate in this State, without it being measured or registered on a meter provided therefor by such gas company, shall be prima facie evidence of intent to violate and of the violation of this section by the person or persons who would receive the direct benefits from the use of the gas without it being measured or registered on a meter as aforesaid. (Amended, Laws 1927, c. 677.)

Sec. 180.—Any person who, with intent to injure or defraud any gas company, body corporate of this State, shall wilfully injure, alter or obstruct, or prevent the action of any meter provided for the purpose of measuring and registering the quantity of gas consumed by or at any burner, orifice or place, or cause or procure any such meter to be injured or altered, or the action thereof to be obstructed or prevented, shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be punished by imprisonment not exceeding six months, or by fine not exceeding $250, or both, in the discretion of the court. The existence of any injury or alteration of such meter which obstructs or prevents the action thereof as aforesaid, shall be prima facie evidence of intent to violate and of the violation of this section by the person or persons who would receive the direct benefits from the use of gas passing through such injured or altered meter. (Amended, Laws 1927, c. 677.)

Fraud Upon Electric Companies, and Damaging, Interfering, or Tampering with the Property of Such Companies

Sec. 180-a.—It shall be unlawful for any person or persons to wilfully connect or disconnect any electrical conductors belonging to any company using or engaged in the manufacture and supply of electric currents for purposes of light, heat and power or either of them, or to make any connection with any such electrical conductors for the purpose of using or wasting the electric current, or to in anywise tamper with any meter used to register current consumed, or to interfere with the operation of any dynamo or other electrical appliance of such company, or to tamper with or interfere with the poles, wires or conduits used by such companies, unless such person or persons shall be duly authorized by or be in the employ of such company; provided, that nothing in this section shall in any way interfere with any lawful supervision and control of electric light and power companies, their electric conductors, appliances, machinery and poles by the municipality within which such companies are doing business, or by the officers of such municipality, nor shall anything in this section interfere with any right now existing in the councils of any municipality to pass ordinances relating to and regulating such electric light and power companies. Any person or persons found guilty of a violation of any of the provisions of this section shall be deemed guilty of a misdemeanor, and shall, upon conviction thereof, be imprisoned not exceeding six months or fined not exceeding $500, or both or either, in the discretion of the court. The existence of any connection, wire, conductor, meter alteration, or any device whatsoever which effects the diversion of electric current without the same being measured or registered by or on a meter installed by any company engaged in the manufacture and supply of electric current for the purposes of light, heat and power, or either of them, or the use of electric current furnished by such company, without it being measured or registered on a meter provided therefor by such company, shall be prima facie evidence of intent to violate and of the violation of this section by the person or persons using or receiving the direct benefits from the use of electric current passing through such connection, wire, conductor, device or altered meter, or being used without being measured or registered on a meter as aforesaid, and in case a check or test meter installed or employed by such company shows that a customer is using a larger amount of electricity than is registered on the meter installed by the company on the customer's premises for the purpose of registering the electricity used by customer, such condition shall constitute prima facie evidence that the unregistered current has been wrongfully diverted by such customer, and shall further constitute prima facie evidence of the intent to violate and of the violation of this section. (Added Laws 1927, c. 677.)

Massachusetts General Laws of 1921

Chapter 164—*Manufacture and Sale of Gas and Electricity*

Sec. 126.—Whoever willfully or fraudulently injures, disconnects, removes or otherwise interferes with, or suffers to be injured, disconnected, removed or otherwise interfered with, any meter, pipes or fitting belonging to a gas company, or prevents a meter from duly registering the quantity of gas supplied through the same, or in any way hinders or interferes with its proper action or just registration, or fraudulently burns or wastes the gas of such company, or whoever attaches a pipe or any appliance to a main or pipe belonging to a gas company or, without the written consent of such company, uses or causes to be used any gas supplied by it, unless the same passes through a meter set by the company, shall be punished by a fine of not more than one hundred dollars or by imprisonment for not more than one year, or both.

Sec. 127.—Whoever unlawfully and intentionally injures or destroys, or suffers to be injured or destroyed, any meter, pipe, conduit, wire, line, pole, lamp or other apparatus belonging to a corporation engaged in the manufacture or sale of electricity or unlawfully and intentionally prevents an electric meter from duly registering the quantity of electricity supplied, or in any way interferes with its proper action or just registration, or, without the consent of such corporation, unlawfully and intentionally diverts any electric current from any wire of such corporation, or otherwise unlawfully and intentionally uses or causes to be used, without the consent of such corporation, any electricity manufactured or distributed by it shall be punished by a fine of not more than $100 or by imprisonment for not more than one year, or both.

In Commonwealth vs. Caroline Shaw, 86 Mass. (4 Allen) 308-309-310, the defendant was indicted for the larceny of several hundred "cubic feet of illuminating gas, each cubic foot being of the value of three mills, of the property, goods and chattels of the Boston Gas Light Co." The gas company, upon the non-payment by the defendant of the gas rates, removed the meter and shut off the gas by closing a stopcock in the service pipe, upon the premises occupied by her and gave her notice thereof; after which she, without the consent or knowledge of the company, and to avoid paying for the gas, made a connection by means of a lead pipe between the service pipe and the pipe inside the house occupied by the defendant, and turned the cock in the service pipe, and received and consumed gas belonging to the company. In affirming a verdict of guilty by a jury, the court said:

> There is nothing in the nature of gas used for illuminating purposes which renders it incapable of being feloniously taken and carried away. It is a valuable article of merchandise bought and sold like other personal property, susceptible of being severed from a mass or larger quantity and of being transported from place to place. In the present case it appears that it was the property of the Boston Gas Light Company; that it was in their possession by being confined in conduits and tubes, which belonged to them, and that the defendant severed a portion of that which was in a pipe of the company by taking it into her house and there consuming it. All this, being proved to have been done by her secretly, and with an intent to deprive the company of their property, and to appropriate it to her own use, clearly constituted the crime of larceny.
>
> It was suggested by the counsel for the defendant that, if she was guilty of any offence, it was not larceny, but embezzlement, inasmuch as it appeared that the gas was intrusted to her possession by the Company, and that at the time of the alleged felonious taking she was the bailee thereof. But the facts proved entirely negative the existence of any such relation between her and the company. The gas was not in her possession. On the contrary, the pipe had been severed from the meter by closing a stopcock in the service pipe, which belonged to the company, for the very purpose of preventing her obtaining possession of it. The fact that the end of the pipe was on the premises occupied by her is wholly immaterial. It was not placed there to be in her custody or control, and she had no possession of it or its contents. The facts proved at the trial are similar to those which were shown to exist in the case of Regina vs. White, 6 Cox C. C. 213, in which a conviction of the defendant for the larceny of gas was affirmed by the court of criminal appeal. That case, however, was not so strong against the defendant as the present one, because it there appeared that the owners of the gas had not caused it to be shut off from the premises of the defendant, to prevent him from making use of it.

Michigan Compiled Laws 1915

Offenses Against Property

Sec. 15361.—Every person who wilfully or fraudulently injures, or suffers to be injured, any meter, wire, line, pipe or appliance belonging to any water, steam, electric or gas company, prevents any water, steam, electric or gas meter belonging to such company from duly registering the quantity of water, steam, electric current or gas measured through the same, or in any way hinders or interferes with its proper action or just registration, or attaches any line, wire or pipe to any line, wire, pipe or main belonging to such water, steam, electric or gas company, or otherwise uses or burns or causes to be burned or used any water, steam, electric current or gas supplied by such company, without the written consent of such company or its duly authorized agent, or officer, unless the same passes through a meter or is measured by a meter set by said company, or fraudulently uses its water, steam, electric current or gas, or wastes the same, shall, for every such offence, if the value of such water, steam, electric current, gas or damage so caused shall not exceed in value the sum of $25, upon conviction thereof, be punished by a fine not exceeding $100 or by imprisonment of not more than 90 days, or by both such fine and imprisonment in the discretion of the court, and if the value of such water, steam, electric current, gas or damage so caused, shall exceed in value the sum of $25, shall upon conviction thereof, be punished by a fine of not exceeding $1,000, or by imprisonment in the State prison for a term of not less than three months nor more than three years, or by both such fine and imprisonment in the discretion of the court: provided, that such criminal prosecution shall not in any way impair the right of such company to a full compensation in damages by civil suit.

Sec. 15362.—The provisions of this act shall extend to and apply to all offences against all water, steam, electric or gas companies and boards or municipalities owning or operating plants for producing, manufacturing, furnishing, transmitting or conducting water, steam, electricity or gas, either natural or artificial.

Sec. 15363—In all prosecutions under this act it shall be prima facie evidence on the part of the people of the violation of the provisions of this act, to show that the respondent other than a lessor had control of or occupied the premises where the offense was committed, or received the benefit of such water, steam, electric current or gas so used or consumed.

Minnesota General Statutes 1923

Injuries to Property

Sec. 10434—Every person who shall wilfully make any connection with any meter, pipe, conduit, wire, line or other apparatus belonging to any person, firm, company or municipality using, or engaged in the manufacture, supply, sales or distribution of electricity, electric current, gas, water or heat, for the purpose of taking, using or wasting such electricity, electric current, gas, water or heat, or shall wilfully prevent any meter from duly measuring or registering the quantity of such commodity supplied, or shall in any way interfere with its proper action or just registration, or shall without the consent of such person, municipality, firm or corporation, wilfully divert any such commodity of such person, municipality, firm or corporation, or in any way wilfully use or cause to be used without the consent of such person, municipality, firm or corporation, any such commodity manufactured or distributed by such person, municipality, firm or corporation, or shall aid, agree with, employ, or conspire with any other person to do any of the said acts, or who shall deposit in any meter or other apparatus used by an electric light or telephone company or other person, municipality, firm or corporation, for the pre-payment for current or service any token, article or device, except lawful coin of the United States, for the purpose of fraudulently obtaining such current or service, shall be guilty of a misdemeanor. (R. L. Sec. 5143, amended '07 c. 166, Sec. 1; L. 1927, c. 298.)

Sec. 9922.—Whoever is convicted of a misdemeanor for which no punishment is prescribed by any statute in force at the time of conviction and sentence shall be punished by imprisonment in the county jail for not more than three months or by a fine of not more than $100.

Hemingway's Annotated Mississippi Code 1927

Sec. 1046.—Whoever, intentionally, by any means or device, prevents electric current, water or gas from passing through any meter or meters belonging to any person, firm or corporation engaged in the manufacture, sale or distribution of electricity, water or gas for lighting, power or other purposes, furnished such persons to register current or electricity, water or gas, passing through meters, or intentionally prevents the meter from duly registering the quantity of electricity, water or gas supplied, or in any manner interferes with its proper action or just registration, or, without the consent of such person, firm or corporation, intentionally diverts any electrical current from any wire or cable, or water or gas from any pipe or main of such person, firm or corporation, or otherwise intentionally uses, or causes to be used, without the consent of such person, firm or corporation, any electricity or gas manufactured, or water produced or distributed by such person, firm or corporation or any person, firm or corporation who retains possession of, or refuses to deliver any meter or meters, lamp or lamps, or other appliances which may be, or may have been, loaned them by any person, firm or corporation for the purpose of furnishing electricity, water or gas, through the same, with the intent to defraud such person, firm or corporation, shall be guilty of a misdemeanor and upon conviction, shall be punished by a fine of not less than $10 and not more than $100, or by imprisonment in the county jail not more than three months, or by both fine and imprisonment in the discretion of the court.

Missouri Revised Statutes 1919, Vol. 1

Offenses Against Property

Sec. 3354—That any person who shall make a connection of any pipe, tube or device to any gas service pipe or main used to carry gas to a gas meter by any gas company furnishing gas for public or private use; or shall efface, puncture, move, remove, reverse or alter any gas meter or the connection thereof, owned or used by such gas company; or shall prevent any such gas meter from properly measuring or registering gas; or shall knowingly take, receive, use or convert to his own use or the use of another any gas which has not been measured; or shall cause, procure, permit, aid or abet any person to do any of the aforesaid acts, shall, upon conviction, be punished by imprisonment in the penitentiary for a term not exceeding two years or by fine not exceeding $500, or by both such fine and imprisonment. The existence of any of the aforesaid pipe connections or meter alterations, or the use of unmeasured gas, shall be prima facie evidence of intent to violate and of the violation of this section by the person or persons using or receiving the direct benefits from the use of the gas passing through such connections or meter, or being used unmeasured as aforesaid. (R. S. 1909, Sec. 4576, 4577, amended laws 1919, p. 260.)

Sec. 3355.—Any person who, without the consent of any person, firm or corporation engaged in the manufacture, distribution and sale of electricity, for public or private use, shall unlawfully and intentionally convert to his own use for the use of another party, from any wire or conductor of such person, firm or corporation, any portion of such electric current or electricity, or who shall unlawfully and intentionally prevent such current, or any portion thereof, from passing through any meter provided for measuring the same by such person, firm or corporation, or who shall in any manner, unlawfully and intentionally, prevent such meter from registering correctly the current passing through it, or aid in any manner the unlawful conversion to his use, or the use of another, of any portion of such electric current, shall be guilty of a misdemeanor, and shall, upon conviction, be punished by a fine of not less than $50 nor more than $500, or by imprisonment in the county jail for not less than three months nor more than twelve months, or by both such fine and imprisonment. (R. S. 1909, Sec. 4578.)

Sec. 3357—Anyone who shall knowingly accept or receive the use and benefit of electric current which should pass through a meter, but has been diverted therefrom, or which has been prevented from being correctly registered by a meter provided therefor, or which has been diverted from the wires or conductors of a person, firm or corporation producing electricity for public or private use, shall be guilty of a misdemeanor. The presence at any time, on or about such meter or meters, wires or conductors of any device whatsoever, which affects the diversion of electric current without the same being measured or registered by the person, firm or corporation producing the same, shall constitute prima facie evidence of knowledge on the part of the person who, as owner or lessee or otherwise at the time, has the use, custody or control of the room or building where such device exists, of the existence thereof and the effect thereof, and shall further constitute prima facie evidence of the intention on the part of such person to defraud and shall bring such person prima facie within the scope, meaning and penalties as prescribed for a misdemeanor, and in case a check meter, installed by any person, firm or corporation vending electricity, registers more current than is registered by the meter installed in a customer's premises, such condition shall constitute prima facie evidence that such unregistered current has been wrongfully diverted by such customer, and shall further constitute prima facie evidence of the intention on the part of such customer to defraud, and shall bring such person prima facie within the scope, meaning and penalties as prescribed for a misdemeanor. (R. S. 1909, Sec. 4580, amended laws 1919, p. 259.)

Montana Revised Codes, Penal, 1921

Larceny of Gas or Electricity

Sec. 11385.—Every person who, with intent to injure or defraud, procures, makes or causes to be made, any pipe, tube, wire or other conductor of gas or electricity, and connects the same, or causes it to be connected, with any main, service pipe or other pipe for connecting or supplying illuminating gas or any wires or other conductor of electricity to any lamp, motor, burner or orifice, by or at which illuminating gas or electricity is consumed, around or without passing through the meter provided for the measuring and registering the quantity consumed, or in any other manner so as to evade payment therefor, and every person who, with like intent, injures or alters any gas or electric meter, or obstructs its action, is guilty of a misdemeanor. In prosecution for offences under this section, proof that any of the acts herein forbidden have been done in, upon or about the premises owned or used by the defendant charged with the commission of such offence in such a manner as to decrease or lessen the amount he should pay under his understanding or contract with any person or corporation engaged in the business of furnishing and selling gas or electricity, shall be prima facie evidence of the guilt of said defendant.

Sec. 10725—Except in cases where a different punishment is prescribed by this code every offence declared to be a misdemeanor is punishable by imprisonment in a county jail not exceeding six months, or by a fine not exceeding $500, or both.

In State ex rel. Deeney vs. Butte Electric & Power Co., 43 Mont. 118, it was held to quote headnote:

Where the answer of defendant company in a proceeding in mandamus to compel it to furnish electricity to relator, failed to allege that it also had a gas franchise, a rule that it would not furnish electricity to one who had stolen gas from its mains until all reasonable bills therefor had been paid was not one which it had a right under its electricity franchise to adopt in protection of its gas business and was therefore no defense to its refusal to supply relator with electric light.

Nebraska Compiled Statutes 1922

(As amended by Chapter 86, Laws of 1923)

Sec. 7116.—Any person who connects any wire, cord, socket, motor, pipe, conduit or other instrument, device or contrivance with any wire transmitting or supplying or intending to transmit or supply electricity, electric current, or connects any pipe or conduit supplying gas or water, without the knowledge and consent of the person, partnership, corporation or company furnishing the electricity or electric current transmitted or supplied by said wire, or gas or water supplied by said pipe or conduit, in such manner that any portion of such electricity, electric current, gas or water may be transmitted or supplied to any globe, lamp, heating apparatus, motor or other instrument, by or at which electricity, electric current, gas or water may be consumed, shall be deemed guilty of a misdemeanor, and, upon conviction, shall be punished as provided in the fourth following section.

Sec. 7117.—Any person who connects or changes any wire, cord, socket, motor, pipe, conduit or other instrument, device or contrivance with any wire, pipe or conduit transmitting or supplying or intended to transmit or supply electricity, electric current, gas or water, without the knowledge and consent of the person, partnership, corporation or company furnishing the electricity, electric current, gas or water transmitted or supplied by said wire, pipe or conduit, in such manner as to transmit or supply any such electricity, electric current, gas or water to any globe, lamp, heating apparatus, motor or other instrument by or at which electricity, electric current, gas or water may be consumed without passing through the meter provided for measuring or registering the amount or quantity of electricity, gas or water passing through it, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished as provided in the third following section.

Sec. 7118—Any person who wilfully injures, alters, or by any instrument, device or contrivance in any manner interferes with, or obstructs, the action or operation of any meter made or provided for measuring or registering the amount or quantity of electricity, gas or water passing through it, without the knowledge and consent of the person, partnership, corporation or company furnishing or supplying the electricity, electric current, gas or water passing or intended to pass through such meter, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished as provided in the next but one following section.

Sec. 7119.—Any person who knowingly uses or who knowingly permits the use of any electricity, electric current, gas or water in any globe, electric motor, heating apparatus or other instrument or device by which electricity, gas or water may be consumed, owned, leased or used by such person, or by any partnership, company or corporation of which such person is a member, officer, representative or agent, when any portion or quantity of such electricity, electric current, gas or water passes through or along any line, cord, socket, motor, pipe, conduit or other instrument, device or contrivance which has been connected with any wire, pipe or conduit transmitting or supplying electricity, gas or water without the knowledge and consent of the person, partnership, corporation or company furnishing the electricity, electric current, gas or water transmitted or supplied by said wire, pipe or conduit, or when any portion or quantity of such electricity, electric current, gas or water passes around, or by, or through any meter provided for measuring or registering the amount or quantity thereof, without being so measured or registered by reason of such meter being changed, interfered with or obstructed without the knowledge and consent of the person, partnership, corporation or company furnishing the electricity, electric current, gas or water, passing or intended to pass through the meter, or by reason of some wire, cord, socket, motor, pipe, conduit or other instrument, device or contrivance having been connected with a transmitting or supplying wire, pipe or conduit, without the knowledge and consent of the person, partnership, corporation or company furnishing the electricity, electric current, gas or water transmitted or supplied by said wire, pipe or conduit, shall be deemed guilty of a misdemeanor, and upon convicton shall be punished as provided in the next following section.

Sec. 7120.—Any person convicted of a violation of any of the provisions of the four next preceding sections shall be punished for such offence by a fine of not less than $50 nor more than $300, or by imprisonment in the county jail for a period of not less than thirty days nor more than ninety days, or by both such fine and imprisonment.

Sec. 7121.—Proof of the existence of any wire, pipe or conduit connection, or of any injury, alteration or obstruction of a meter, as in the foregoing sections, provided, shall be taken as prima facie evidence of the guilt of the person in possession of the premises where such connection, injury, alteration or obstruction is proven to exist.

Nevada Revised Laws 1912

Crimes and Punishments

Sec. 6733—Every person who wilfully, and with intent to injure or defraud:

1. Opens, breaks into, taps or connects with any pipe, flume, ditch, conduit, reservoir, wire, meter or other apparatus belonging to or used by any water, gas, irrigation, electric or power company or corporation, or belonging to or used by any other person, persons or association, or by the State, or by any county, city, district or municipality, and takes and removes therefrom, or allows to be taken, removed or flow therefrom, any water, gas, electricity or power belonging to another; or,

2. Connects a pipe, tube, flume, conduit, wire or other instrument or appliance with any pipe, conduit, tube, flume, wire, line, pole, lamp, meter or other apparatus belonging to or used by any water, irrigation, gas, electric or power company or corporation, or belonging to or used by any other person, persons or association, in such manner as to take therefrom water, gas, electricity or power for any purpose or use, without passing through the meter, or instrument, or other means provided for registering the quantity consumed or used; or,

3. Destroys, detaches, disconnects, alters, injures or prevents the action of a head-gate, meter or other instrument or means used to measure or register the quantity of water, gas, electricity or power consumed or supplied; or,

4. Injures or destroys, or interferes with the efficiency or use, or suffers to be injured or destroyed, any pipe, conduit, flume. wire, pole, line, lamp, fixture, hydrant or other attachment or apparatus belonging to or used by any water, irrigation, gas, electric or power company or corporation, or belonging to and used by any other person, persons or association;

Is guilty of a misdemeanor, and, upon conviction thereof, shall be punished by a fine not exceeding $500, or by imprisonment in the county jail not to exceed six months, or by both such fine and imprisonment, in the discretion of the court; and shall, moreover, be liable to the person, persons, association or corporations, or the owner or user whose property is injured, in a sum equal to treble the amount of actual damages sustained thereby.

New Hampshire Public Laws, 1926

Chapter 355, *Sec.* 7

Whoever shall wantonly and maliciously injure or destroy, or cause to be injured or destroyed, any meter, pipe, conduit, wire, line, post, lamp or other apparatus belonging to a person or corporation engaged in the manufacture or sale of electricity, or shall wantonly and maliciously prevent an electric meter from duly registering the quantity of electricity supplied, or cause it to be done, or shall wantonly and maliciously interfere with its proper action or just registration, or without the consent of such person or corporation shall wantonly and maliciously divert electric current from any of their wires, or shall cause it to be done, or shall otherwise wantonly and maliciously use or cause to be used the electric current from such wire, shall, except as otherwise provided, be fined not more than $300 and shall pay treble damages to such person or corporation.

New Jersey Compiled Statutes 1709-1910

Crimes

Sec. 164.—Any person who shall, without permission, connect by wire or in any other manner with the wire or wires of an electric light or other electric company, or who shall, without permission, connect or disconnect the meters, pipes or conduits of any gas or water company, or in any other manner without such permission tamper or interfere with such meters, pipes or conduits, or who shall, without such permission, connect with the meter, pipes or conduits of such company by pipes, conduits or other instrument, for the purpose of obtaining power or electric current or gas or water with intent to defraud such company or companies, shall be guilty of a misdemeanor. (P. L. 1898, p. 839, as amended P. L. 1903, p. 388.)

Sec. 218.—Any person found guilty of any crime which by this or any other statute is declared to be a misdemeanor, shall be punished by a fine not exceeding $1,000, or by imprisonment, with or without hard labor as the court may direct, for any term not exceeding three years, or both. (P. L. 1898, p. 854.)

Sec. 164-a.—Whoever shall without permission or authority connect or cause to be connected by a wire or wires, or by any other device with the wires, cables or conductors of any electric company for the purpose of obtaining electric current for light, heat or power; or, whoever shall, without permission or authority, connect or cause to be connected by wires or other devices any meter or meters erected or set up for the purpose of registering or recording the amount of electric current supplied to any customer by any electric company within this State, or change or shunt the wiring leading to or from any such meter, or by any device, appliance or means whatsoever tamper with any such meter in such a manner that such meter or meters will not measure or record the full amount of electric current supplied to such customer shall be guilty of a misdemeanor, and on conviction thereof shall be punished by a fine not exceeding $500 or imprisonment at hard labor for any term not exceeding six months, or both; provided, that nothing herein contained shall be deemed to effect the right of any person or corporation to recover by an action at law damages for any injury done by such unlawful connection for the loss of electric power. (P. L. 1899, p. 210.)

In State v. Block, 70 N. J. L. 398, Block was convicted of a misdemeanor upon an indictment based upon the statute to punish persons who unlawfully obtain electric current. In sustaining the judgment the court held, to quote the headnote:

Upon the trial of an indictment under the act of March 22, 1899 (Pamph. L., p. 210), which charged the defendant with having unlawfully tampered with the meter of an electric light company which supplied him with electric light, thereby preventing the meter from recording or measuring the full amount of the current supplied to him, fixing the date of the offence Sept. 3, 1902, it was satisfactorily proven that on the day named the meter was found to have been tampered with by removing the seal and inserting a pin between the disk and magnets, so that although the current was passing to the lights which were burning, the disk did not rotate and cause the current to be recorded or measured, as it was its office to do; so that the only question left for the jury was as to whether the defendant had been connected with the tampering with the meter. The defendant offered to prove by the books of the company the amounts charged to him during the years 1901, 1902 and 1903 with the purpose of showing the absence of any discrepancy in the amount charged for the month during which the tampering occurred, and also for the purpose of effecting the credibility of a witness for the State. The offer was overruled by the trial judge. Held, on error, that the evidence offered, if relevant at all, bore so remotely upon the issues involved, that its admission or rejection was within the discretion of the trial judge, so that its rejection was no ground for reversal.

New Mexico Statutes Annotated 1915

Injuring Property

Sec. 1579.—Any person who shall willfully or maliciously affix, attach to, or connect with any electric power transmission line in the State of New Mexico any article or thing whereby leakage, or loss of electric current from said line shall or may be effected, and any person who shall willfully or maliciously by any means cause leakage or loss of electric current from any such power transmission line, shall be deemed guilty of a misdemeanor and, upon conviction thereof, shall be punished by a fine of not more than $100, or by imprisonment in the county jail not more than thirty days, or by both such fine and imprisonment.

New York Penal Law

Larceny

Sec. 1293-c.—Any person who shall operate or cause to be operated, or who shall attempt to operate or attempt to cause to be operated any automatic vending machine, slot machine, coin box telephone or other receptacle designed to receive lawful coin of the United States of America in connection with the sale, use or enjoyment of property or service, by means of a slug or of any false, counterfeited, mutilated or sweated coin, or by any means, method, trick or device whatsoever not lawfully authorized by the owner, lessee or licensee of such machine, coin box, telephone or receptacle; or who shall take, obtain or receive from or in connection with any automatic vending machine, slot machine, coin box telephone or other receptacle designed to receive lawful coin of the United States of America in connection with the sale, use or enjoyment of property or service, any goods, wares, merchandise, gas, electric current, article of value, or the use or enjoyment of any telephone or telegraph facilities or service, or of any musical instrument, phonograph or other property, without depositing in and surrendering to such machine, coin box telephone or receptacle, lawful coin to the amount required therefor by the owner, lessee or licensee of such machine, coin box telephone or receptacle, shall be guilty of a misdemeanor and punishable by imprisonment for not more than six months, or by a fine of not more than $250, or by both fine and imprisonment. (Added by L. 1916, ch. 367.)

Sec. 1431.—A person who willfully, with intent to injure or defraud:

1. Connects a tube, pipe, wire or other instrument or contrivance with a pipe or wire used for the conducting or supplying illuminating gas, fuel, natural gas or electricity in such a manner as to supply such gas or electricity to any burner, orifice, lamp or motor where the same is or can be burned or used without passing through the meter or instrument provided for registering the quantity consumed, or uses such gas or electricity obtained by reason of the making of such connection; or,

2. Obstructs, alters, injures or prevents the action of a meter or other instrument used to measure or register the quantity of illuminating fuel, natural gas or electricity consumed in a house or apartment, or at an orifice or burner, lamp or motor, or by a consumer or other person or a person other than a State inspector or deputy inspector of gas meters or an employee of the company owning any gas or electric meter, who willfully shall detach or disconnect such meter, or make or report any test of, or examine for the purpose of testing any such meter so detached, or disconnected; or,

3. In any manner whatever changes, extends or alters any service or other pipe, wire or attachment of any kind, connecting or through which natural or artificial gas or electricity is furnished from the gas mains or pipes or wires of any person, company or corporation without first procuring from said person, company or corporation written permission to make such change, extension or alterations, or uses gas or electricity obtained by reason of such changes, extensions or alterations without first procuring the written permission aforesaid; or,

4. Makes any connection or re-connection with the gas mains, service pipes or wires of any person, company or corporation furnishing to consumers natural or artificial gas or electricity; or turns on or off or in any manner interferes with any valve or stopcock or other appliances belonging to such person, company or corporation, and connected with its service or other pipes or wires, or enlarges the orifice of mixers, or uses natural gas for heating purposes except through mixers, or uses electricity or artificial gas for any purpose before it has passed through an instrument for measuring the quantity consumed, without first procuring from such person, company or corporation a written permit to turn on or off such stopcock or valve, or to make such connections or re-connections or to enlarge the orifice of mixers or to use for heating purposes without mixers, or to interfere with the valves, stopcocks, wires or other appliances of such person, company or corporation as the case may be; or,

5. Retains possession of or refuses to deliver any mixer or mixers, meter or meters, lamp or lamps or other appliances which may be or may have been loaned or rented to them by any person, company or corporation for the purpose of furnishing gas, electricity or power through the same, or who sells, loans or in any manner disposes of the same to any person or persons other than the said person, company or corporation entitled to the possession of the same; or,

6. Sets on fire any gas escaping from wells, broken or leaking mains, pipes, valves or other appliances used by any person, company or corporation in conveying gas to consumers, or interferes in any manner with the wells, pipes, mains, gate-boxes, valves, stopcocks, wires, cables, conduits, or any other appliances, machinery or property of any person, company or corporation engaged in furnishing gas to consumers unless employed by or acting under the authority and direction of such person, company or corporation; or,

7. Opens or causes to be opened or re-connects or causes to be re-connected any valve lawfully closed or disconnected by a district steam corporation; or,

8. Turns on steam or causes it to be turned on, or to reenter any premises when the same has been lawfully stopped from entering such premises, is guilty of a misdemeanor.

Sec. 1431-a.—The existence of any of the conditions with reference to meters, or attachments described in Sec. 1431 of this article is presumptive evidence that the person to whom gas, electricity, water or steam is at the time being furnished by or through such meters or attachments has, with intent to defraud created or caused to be created with reference to such meters or attachments, the condition so existing. (Added L. 1926, ch. 849.)

Sec. 1937.—A person convicted of a crime declared to be a misdemeanor, for which no other punishment is specially prescribed by this chapter, or by any other statutory provision in force at the time of the conviction and sentence, is punishable by imprisonment in a penitentiary or county jail for not more than one year, or by a fine of not more than $500, or by both.

In the People vs. Wilber, 4 Parker (N. Y.) Criminal Reports 19, it was held to quote the head notes:

In the indictment under the first section of chapter 109 of the Laws of 1854, entitled, "An Act for the protection of gas light companies," it is not sufficient to charge the act complained of in the words of the statute.

The relations of the party, whom it is alleged the defendant intended to defraud, to the means by which the fraud is sought to be perpetrated, must be alleged, so that the court can judicially see that the act complained of is calculated, as well as intended, to defraud; and where an indictment alleged, in the words of the statute, that the defendant connected certain pipes, etc., with intent to defraud a gas company, and contained no allegation, that the company supplied the gas consumed at the burners; held that the indictment was defective.

Whether the bare mention of the name of a gas company in an indictment, necessarily implies an allegation of its corporate existence; *cuere*.

The general rules of pleading, and the exceptions thereto, as applicable to an indictment under this statute, and what such an indictment should contain, discussed and stated.

North Carolina Code 1927

Interfering with Gas and Electric Appliances

Sec. 4323.—If any person shall willfully, with intent to injure or defraud, commit any of the acts set forth in the following subsections, he shall be guilty of a misdemeanor:

1. Connect a tube, pipe, wire or other instrument or contrivance with a pipe or wire used for conducting or supplying illuminating gas, fuel, natural gas or electricity in such a manner as to supply such gas or electricity to any burner, orifice, lamp or motor where the same is or can be burned or used without passing through the meter or other instrument provided for registering the quantity consumed; or,

2. Obstruct, alter, injure or prevent the action of a meter or other instrument used to measure or register the quantity of illuminating fuel, natural gas or electricity consumed in a house or apartment, or at an orifice or burner, lamp or motor, or by a consumer or other person other than an employee of the company owning any gas or electric meter, who willfully shall detach or disconnect such meter, or make or report any test of, or examine for the purpose of testing any meter so detached or disconnected; or,

3. In any manner whatever change, extend or alter any service or other pipe, wire or attachment of any kind, connecting with or through which natural or artificial gas or electricity is furnished from the gas mains or pipes of any person, without first procuring from said person written permission to make such change, extension or alterations; or,

4. Make any connection or reconnection with the gas mains, service pipes or wires of any person, furnishing to consumers natural or artificial gas or electricity, or turn on or off or in any manner interfere with any valve or stopcock or other appliance belonging to such person, and connected with his service or other pipes or wires, or enlarge the orifice of mixers, or use natural gas for heating purposes except through mixers, or electricity for any purpose without first procuring from such person a written permit to turn on or off such stopcock or valve, or to make such connection or reconnections, or to enlarge the orifice of mixers, or to use for heating purposes without mixers, or to interfere with the valves, stopcocks, wires or other appliances of such, as the case may be; or,

5. Retain possession of or refuse to deliver any mixer, meter, lamp or other appliance which may be leased or rented by any person, for the purpose of furnishing gas, electricity or power through the same, or sell, lend or in any other manner dispose of the same to any person other than such person entitled to the possession of the same.

Sec. 4173.—All misdemeanors, where a specific punishment is not prescribed shall be punished as misdemeanors at common law; but if the offense be infamous, or done in secrecy and malice, or with deceit and intent to defraud, the offender shall be punished by imprisonment in the county jail or State prison for not less than four months nor more than ten years, or shall be fined.

North Dakota Compiled Laws 1913

Larceny

Sec. 9927.—Every person who, with intent to defraud, makes, or causes to be made, any pipe or other instrument or contrivance, and connects the same, or causes it to be connected, with any pipe laid for illuminating gas, so as to conduct gas to a point where the same may be consumed without its passing through the meter provided for registering the quantity consumed, or in any other manner so as to evade paying therefor, and every person who with like intent injures or alters any gas meter or obstructs its action, is guilty of a misdemeanor. (R. C. 1905, Sec. 9200; Pen. C. 1877, Sec. 594; R. C. 1899, Sec. 7459.)

Fraudulently Using Electric Current

Sec. 9942.—Every person who, with intent to defraud, makes or causes to be made, any wires or other instruments or contrivances or connection, and connects the same, or causes it to be connected, with any wire laid or strung for conducting electric current, so as to conduct or carry electric current to a point where the same may be consumed without its passing through the meter provided for registering the quantity consumed or in any manner to evade paying therefor, and every person who with like intent injures or alters any electric meter or any electrical appliance, instrument, wire or connection, or obstructs their action, is guilty of a misdemeanor. (1907, ch. 248.)

Sec. 9205.—Except in cases where a different punishment is prescribed by this code or by some existing provisions of law, every offence declared to be a misdemeanor is punishable by imprisonment in a county jail not exceeding one year, or by a fine not exceeding $500, or by both such fine and imprisonment. (R. C. 1905, Sec. 8542; Pen. C. 1877, Sec. 14; R. C. 1895, Sec. 6812.)

Throckmorton's Ohio General Code Annotated 1926

Gas Companies

Sec. 9337.—Every person who willfully or fraudulently injures, or suffers to be injured, a meter belonging to a gas company, or prevents a meter from duly registering the quantity of gas supplied through it, or hinders or interferes with its proper action or just registration, or attaches a pipe to a main or pipe belonging to such company, or otherwise burns or uses or causes to be used gas supplied by such company, without the written consent of an officer thereof, unless it passes through a meter set by the company; or fraudulently burns the gas of the company, or wastes it, for every such act shall forfeit and pay to the company not more than $100, to be recovered in an action brought by it against such offender, and in addition thereto pay the company the amount of damage by it sustained by reason of such injury, prevention, waste, consumption or hindrance. (R. S. Sec. 3560.)

Offenses Pertaining to Property

Sec. 12507.—Whoever willfully or maliciously injures or destroys or intentionally permits to be injured or destroyed, disconnects, displaces, cuts, breaks, taps, grounds, or makes a connection with, or willfully or maliciously interferes with any pole, pier, cable, tower, wire, legally erected, put or strung, electrical apparatus, appliances or machinery used in the construction or operation of an electrical railway, electric light plant, plant used in generating or transmitting electricity, or any meter, pipe, conduit, wire, line, post, lamp, burner, heater, machine, motor or other appliance or apparatus, used in the construction or operation of any such electrical railway or electrical plant, or willfully or maliciously prevents any electric meter used in the construction or operation of such electrical railway or electrical plant, from duly registering the quantity of electricity supplied, or interferes with the proper action or just registration by such meter, or alters the index in such meter, or, without the consent of the owner of such electrical railway or electrical plant, willfully or maliciously diverts electric current from any such wire or otherwise willfully or maliciously uses or causes to be used without the consent of the owner of such electrical railway or electrical plant, electricity manufactured or distributed by any such electrical railway or electrical plant, shall be fined not less than $50 nor more than $1,000, or imprisoned not less than thirty days nor more than one year, or both. (R. S. Sec. 3467a.)

Sec. 12508.—Whoever, having in his possession or under his control a meter used in the construction or operation of an electrical railway, electric light plant, or plant used in generating or transmitting electricity, willfully permits any person unlawfully and without consent of the owner of such meter to disconnect, change, alter or interfere with the wires running into such meter so as to divert current and prevent such meter from duly registering the quantity of electricity supplied or willfully or maliciously aids, agrees with, employs or conspires with any person to do any of the aforementioned acts, shall be fined not less that $50 nor more than $1,000, or imprisoned not less than thirty days nor more than one year, or both. (R. S. Sec. 3467a.)

Sec. 12512.—Whoever, not the agent or employee for that purpose of the owner, manufacturer or operator thereof, maliciously opens, closes, adjusts or interferes with a valve, regulator, gauge, gate, disk, curb cock, stopcock, meter or other regulating, operating or measuring device or appliance in or attached to the wells, tanks, conduits, pipe-lines, mains, service-pipes, house-pipes, display-pipes or other pipes of a gas company, manufacturer or furnisher of gas with intent to cause the escape of gas or to injure or destroy such property, or maliciously enlarges or alters a mixer furnished or approved by a gas company, manufacturer or furnisher of gas to or for a consumer of gas, or maliciously removes from its connection a mixer so furnished or approved, or, without express permission first obtained, consumes for fuel the gas of a gas company, manufacturer or furnisher of gas without the use of a mixer so furnished or approved by such gas company, manufacturer or furnisher of gas, or taps, severs or opens a main or pipe used or intended for the transmission of gas or connects with such main or pipe any other main or pipe, shall be fined not less than $25 nor more than $300, or imprisoned not more than thirty days, or both. (88 v. 241, Sec. 1.)

Oklahoma Compiled Statutes Annotated 1921

Larceny

Sec. 2114.—Any person who, with intent to defraud, makes or causes to be made, any pipe or other instrument or contrivance, and connects the same, or causes it to be connected, with any pipe laid for conducting illuminating gas, so as to conduct gas to a point where the same may be consumed without its passing through the meter providing for registering the quantity consumed, or in any other manner so as to avoid paying therefor, and every person who, with like intent, injures or alters any gas meter, or obstructs its action, is guilty of a misdemeanor.

Sec. 1508.—Except in cases where a different punishment is prescribed by this chapter or by some existing provisions of law, every offence declared to be a misdemeanor is punishable by imprisonment in the county jail not exceeding one year or by a fine not exceeding $500, or by both such fine and imprisonment.

Oregon Laws 1920

Crimes Against Property

Sec. 1992.—Any person who willfully or maliciously with intent to injure or defraud:

1. Connects a tube, pipe, wire or other instrument or contrivance with a pipe or wire used for the conducting or supplying of illuminating gas or fuel or electricity in such a manner as to supply such gas or electricity to any burner, orifice, lamp or motor where the same is or can be burned or used, without passing through the meter or instrument provided for registering the quantity consumed; or,

2. Obstructs, alters, injures or prevents the action of a meter or other instrument used to measure or register the the quantity of illuminating gas or fuel or electricity consumed or used in a building, house, department or office, or at any orifice or burner, or lamp or motor, or by a lawful consumer; or any person other than a city official, inspector or deputy inspector, or an employee of the company owning any gas or electric meter, who willfully shall detach or disconnect such meter, or make or report any test, or examine for the purpose of testing any such meter so detached or disconnected; or,

3. In any manner whatever changes, extends or alters any service or other pipe, wire or attachment of any kind connecting or through which artificial gas or electricity is furnished from the gas mains or pipes or wires of any person, company or corporation, without procuring from said person, company or corporation written permission to make such change, extension or alteration; or,

4. Makes any connection or re-connection with the gas mains, service pipes or wires of any person, company or corporation furnishing to consumers gas or electricity, or turns on or off or in any manner interferes with any valve or stopcock or other appliances belonging to such person, company or corporation, and connected with its service or other pipes or wires, or uses electricity for any purpose without first procuring from such person, company or corporation a written permit to turn on or off such stopcock or valve, or to make such connections or re-connections, or to interfere with the valves, stopcocks, wires or other appliances of such person, company or corporation, as the case may be; or,

5. Retains possession of or refuses to deliver any meter or meters, lamp or lamps, or other appliances which may be or may have been loaned or rented to them by any person, company or corporation for the purpose of furnishing gas, electricity or power through the same, or who sells, loans or in any manner disposes of the same to any person or persons other than the said person, company or corporation entitled to the possession of the same; or,

6. Sets on fire any gas escaping from leaking mains, pipes, valves or other appliances used by any person, company or corporation in conveying gas to consumers, or interferes in any manner with the pipes, mains, gate boxes, valves, stopcocks, wires, cables, conduits or any other appliances, machinery or property of any person, company or corporation engaged in furnishing gas or electricity to consumers, unless employed by or acting under the authority or direction of such persons, company or corporation; or,

7. Without lawful authority displaces, removes, injures, interferes with, alters or destroys any lawfully connected line or lines of wire or cable, or any material, property or apparatus belonging thereto used for conducting or transmitting electricity, for any purpose whatsoever, or cuts, breaks, taps or makes connections with any such line or lines or wire or cable, or material, property or apparatus; or,

8. Breaks, injures, interferes with, alters or destroys any arc or incandescent lamps or their appurtenances, or any gas lamp lawfully used for lighting any street, road, public place or private place; or,

9. Aids, assists, agrees with, employs or conspires with any person or persons to do or causes to be done or permitted any of the acts hereinabove mentioned which by this act is made punishable, shall be punished by imprisonment in the county jail not less than thirty days nor more than one year, or by imprisonment in the penitentiary not less than six months nor more than two years, or by fine not less than $50 nor more than $500, or by both such imprisonment and fine.

Digest of Pennsylvania Statute Law 1920

Electric Light, Heat and Power Companies

Sec. 5867.—That it is hereby made unlawful for any person or persons to connect or disconnect any electrical conductors belonging to any company, using or engaged in the manufacture and supply of electric current for purposes of light, heat and power, or either of them, or to make any connection with any such electrical conductors for the purpose of using or wasting the electric current, or to in any wise tamper with any meter used to register current consumed, or to interfere with the operating of any dynamo or other electrical appliance of such company, or to tamper with or interfere with the poles, wires or conduits used by such companies, unless such person or persons shall be duly authorized by or be in the employ of such company. Provided, that nothing in this act shall in any way interfere with any lawful supervision and control of electric light and power companies, their electric conductors, appliances, machinery and poles by the municipality within which such companies are doing business, or by the officers of such municipality, nor shall anything in this act interfere with any right now existing in the councils of any municipality, to pass ordinances relating to and regulating such electric light and power companies. (1895, June 25; P. L. 302, Sec. 1.)

Sec. 5868.—That any person or persons found guilty of a violation of any of the provisions of Sec. 1 of this act shall be deemed guilty of a misdemeanor, and shall, upon conviction thereof, be imprisoned not exceeding one year, or fined not exceeding $1,000, or both, or either, at the discretion of the court. (1895, June 25; P. L. 302, Sec. 2.)

Sec. 5869.—Any person who injures or destroys, or permits to be injured or destroyed, any meter, pipe, conduit, wire, line, pole, lamp, motor, generator or other apparatus belonging to any company using, or engaged in the manufacture or sale of electricity for the purpose of light, heat and power, or either of them; or any person, who is a consumer or customer, who shall knowingly have in his possession or under his control an electric meter which has been tampered with, or prevented from duly registering the quantity of electricity supplied or consumed; or any person who shall in any way interfere, or permit any interference, with the proper action and just registration of any meter, or who shall, without the consent of such company or corporation, divert any electric current from any wire of such company; or otherwise to use or cause to be used, without the consent of such company, any electricity manufactured or supplied by such company, shall for every such offence be deemed guilty of a misdemeanor, and shall be, upon conviction thereof, imprisoned not exceeding six months, or fined not exceeding $100, or both or either, at the discretion of the court: Provided, that nothing in this act shall in any way interfere with any lawful supervision or control of electric light and power companies, their electric conductors, appliances, machinery and poles, by the municipality within which the said companies are doing business, or by the officers of such municipality nor shall anything in this act interfere with any right now existing in the councils of any municipality to pass ordinances relating to regulating such electric light and power companies. (1911, June 8; P. L. 716, Sec. 1.)

Gas and Water Companies

Sec. 5921.—Whoever, except the authorized agent or employee for the purpose of the owner, manufacturer or operator thereof, maliciously opens, closes or in any manner or to any extent adjusts or interferes with any valve, regulator, gage, gate, disk, curb cock, stopcock, meter or other regulating, operating or measuring device or appliance in or attached to the wells, tanks, conduits, pipe lines, mains, service pipes, house pipes, display pipes or other distributing pipes of any gas company, manufacturer or furnisher of gas, with the intent to cause the escape of any gas or to injure or destroy any of such property, or maliciously enlarges or alters any mixer, furnished or approved by any gas company, manufacturer or furnisher of gas, to or for a consumer of its, his or their gas, or maliciously removes from its connection any mixer so furnished or approved of, or puts on any mixer without express permission first obtained, or consumes for fuel or light the gas of any gas company, manufacturer or furnisher of gas, or taps, severs or opens any main or pipe used or intended for the transmission of gas, or connects with such main or pipe any other main or pipe, shall be deemed guilty of a misdemeanor, and upon conviction thereof be sentenced to pay a fine not exceeding $300 or undergo an imprisonment not exceeding three months, or both, or either, at the discretion of the court. (1895, June 26; P. L. 319, Sec. 1.)

Rhode Island General Laws of 1923

Offenses Against Private Property

Sec. 6109.—Every person who, with intent to injure or defraud any gas light company or any corporation supplying water in this State at a stipulated rate of payment, shall make or cause to be made any pipe, tube or other instrument or contrivance, and connect the same or cause the same to be connected with any main, service pipe or other pipe, appliance or appurtenance used for or in connection with the works or apparatus employed for conducting or supplying illuminating gas or water, in such manner as to be calculated to supply such gas or water to any burner, orifice, faucet or other outlet whatsoever, without such gas or water passing through a meter provided or used for measuring or registering the quantity thereof so passing through, or without the consent of said company or corporation to such connections aforesaid, or who shall otherwise use any such gas or water with the intent to defraud said company or corporation of payment therefor, shall be deemed guilty of a misdemeanor and shall be imprisoned not exceeding thirty days or be fined not exceeding $100.

Sec. 6110.—Every person or corporation who shall wilfully collect of any person or persons a larger sum for gas or water than appears to be due on inspection of the meter put in to regulate and register the same, or shall wilfully furnish a meter that shall not correctly register the quantity of gas or water so consumed, shall be fined not exceeding $500.

Sec. 6124.—Every person who, with intent to injure or defraud any person, persons, association or corporation generating, conducting, using or supplying the electric current, either for the purpose of his, its or their own business, or for the purpose of selling such electric current at a stipulated rate of payment, shall make or cause to be made, any wire or other instrument or contrivance and connect the same or cause the same to be connected with any electric wire, appliance, apparatus or appurtenance used for or in connection with the wires supplying such electric current, in such manner as to be calculated either to waste and dissipate such electric current or to supply such electric current to any lamp, burner, heater, machine, motor or other apparatus or appliance whatsoever, without such electric current passing through a meter provided by said person, persons, association or corporation, and used for registering the quantity thereof so passing through, or without the consent of said person, persons, association or corporation to such connections aforesaid, or who shall otherwise use any such electric current with the intent to defraud said person, persons, association or corporation of payment therefor, shall be deemed guilty of a misdemeanor, and shall be imprisoned not exceeding thirty days or be fined not exceeding $100.

South Carolina Code of Laws 1922, Criminal Laws

Offenses Against Property

Sec. 49 (21).—Any person who has no contract, agreement, license or permission with or from any person or corporation authorized to manufacture, sell or use electricity for the purpose of light, heat or power, or with or from any authorized agent of such person or corporation for the use of electrical current belonging to, or produced or furnished by, any such person or corporation, who shall wilfully withdraw, or cause to be withdrawn, in any manner, and appropriate such current from the wires of any such person or corporation, for his own use, or for the use of any other person or corporation, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding $100, or by imprisonment not exceeding thirty days, or by both such fine and imprisonment. And any person who shall aid, abet or assist such other person in such withdrawing and appropriating of such current from such wires to or for the use of such other person, or to or for the use of any other person or corporation, shall be guilty of a misdemeanor and shall, upon conviction, be punished in like manner.

Sec. 50 (22).—Any person who has no contract, agreement, license or permission with or from any person or corporation authorized to manufacture, sell or use gas for the purpose of light, heat or power, or with or from any authorized agent of such person or corporation, for the use of gas belonging to, or produced or furnished by, any such person or corporation, who shall wilfully withdraw, or cause to be withdrawn, in any manner and appropriate such gas from the pipes or conduits of any such person or corporation, for his own use, or for the use of any other person or corporation, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine not exceeding $100, or by imprisonment not exceeding thirty days, or by both such fine and imprisonment. Any person who shall aid, abet or assist such other person in such withdrawing and appropriating of such gas from such pipes or conduits to or for the use of such other person, or to or for the use of any other person or corporation, shall be guilty of a misdemeanor and shall, upon conviction, be punished in like manner.

Sec. 51 (23).—Any person who has a contract, agreement, license or permission, oral or written with or from any person or corporation authorized to manufacture, sell or use gas for the purpose of light, heat or power, or with or from any authorized agent of same, for the use of the gas belonging to, or produced or furnished by, any such person or corporation, for certain specified purposes, who shall wilfully and intentionally withdraw, or cause to be withdrawn, in any manner and appropriate to his own use, or to the use of any other person or corporation, for purposes other than specified, shall be guilty of a misdemeanor and, upon conviction thereof, shall be punished as provided in Sec. 22 of this chapter. And any such person to whom such gas is furnished from or by means of a meter, who shall wilfully and with intention to cheat and defraud any of said persons or corporations, alter or interfere with such meter, or by any contrivance whatsoever withdraw or take off gas in any manner except through such meter, shall be guilty of a misdemeanor, and punished as provided in Sec. 22 of this Chapter.

Sec. 52 (24).—Any person who has a contract, agreement, license or permission, oral or written, with or from any person or corporation authorized to manufacture, sell or use electricity for the purpose of light, heat or power, or with or from any authorized agent of the same, for the use of the electrical current belonging to, or produced or furnished by, any such person or corporation, for certain specified purposes, who shall wilfully and intentionally withdraw, or cause to be withdrawn, in any manner, and appropriate to his own use, or to the use of any other person or corporation, for purposes other than those specified, shall be guilty of a misdemeanor and, upon conviction thereof, shall be punished as provided in Sec. 21 of this Chapter. And any such person to whom such electrical current is furnished from or by means of a meter, who shall wilfully and with intention to cheat and defraud any of said persons or corporation, alter or interfere with such meter, or by any contrivance whatsoever withdraw or take off electrical current in any manner except through such meter, shall be guilty of a misdemeanor, and be punished as provided in Sec. 21 of this Chapter.

South Dakota Revised Code 1919

Miscellaneous Crimes

Sec. 4396.—Any person who shall, without lawful authority, connect or cause to be connected, with any main or service pipe or conductor of any gas, water or electric company, private or municipal, any pipe, wire or other device for the purpose of obtaining gas, water or electrical current therefrom; or who shall, with intent to defraud, connect or cause to be connected, with any meter installed by such company for the purpose of registering the amount of gas, water or electricity supplied to any customer, any pipe, wire or other device, or disconnect, change or in any manner so interfere with any such meter or any pipe, wire or appliance connected therewith, as that such meter will not measure or register the full amount of gas, water or electricity supplied to any customer, shall be guilty of a misdemeanor and, upon conviction thereof, shall be punished by a fine of not exceeding $100 or by imprisonment in the county jail for not exceeding sixty days, or by both such fine and imprisonment.

Sec. 4397.—Nothing contained in the preceding section shall be deemed to affect the right of any such company or corporation to recover, by an action at law, for the loss of gas, water or electricity, or any injury caused by such unlawful connection.

Sec. 4398.—Any person employed to read meters who knowingly reports to his employer that any consumer of gas, water or electricity has used a greater quantity of gas, water or electricity than the amount actually used by said consumer, shall be punished by imprisonment in the county jail not exceeding three months, or by a fine not exceeding $250, or both; and any person who shall knowingly collect from any consumer of gas, water or electricity an amount greater than that actually used by such customer, shall be punished by a fine not exceeding $500.

Tennessee Annotated Code 1918

Trespasses on Property, and Malicious Mischief

Sec. 6506 (8).—It is a misdemeanor in any person wilfully to injure, remove or destroy any turnpike or plank road; or wilfully to cut, burn or in any way break down, injure or destroy any telegraph post, wires or other apparatus thereto belonging; or wilfully to injure, remove or destroy any gas fixture or other property of any gas company.

Sec. 6507.—Any person convicted of any of the foregoing offences enumerated in this article shall be punished by fine not less than $10 (where not otherwise provided).

Sec. 6507a1.—It shall be unlawful for any person, firm or corporation to tap off of, or use without authority, or to wilfully cut, break down or otherwise interrupt or interfere with the current, lines, poles or appliances of an electric light and power company, or any company engaged in furnishing light, heat or power by electricity. (1897. Ch. 102, Sec. 1.)

Sec. 6507a2.—Any such cutting, breaking down, interruption or interference shall be a misdemeanor, punishable by a fine of not less than $5 nor more than $50, or imprisonment in the county workhouse, if there be such, or in the county jail, if there be no workhouse in such county, for a period of not less than ten days nor more than twelve months, for each and every offence, or both, at the discretion of the court. (1897, Ch. 102, Sec. 2.)

Texas (Vernon's) Annotated Penal Code, 1926

Diverting from Meters

Art. 1056.—Whoever, intentionally, by any means or device, prevents electric current, water or gas from passing through any meter belonging to a person, corporation or company engaged in the manufacture or sale of electricity, water or gas for lighting, power or other purposes, furnished such person to register the current of electricity, water or gas, passing through meters, or intentionally prevents a meter from duly registering the quantity of electricity, water or gas supplied, or in any way, interferes with its proper action or just registration, or without the consent of such person, corporation or company, intentionally diverts any electric current from any wire, or water or gas from any pipe or pipes of such person, corporation or company, or otherwise intentionally uses, or causes to be used, without the consent of such person, corporation or company any electricity or gas manufactured, or water produced or distributed, by such person, corporation or company, or any person who retains possession of, or refuses to deliver, any meter, lamp, or other appliances which may be, or may have been loaned them by any person, corporation or company for the purpose of furnishing electricity, water or gas, through the same, with the intent to defraud such person, corporation or company, shall for every such offense be fined not less than $25 nor more than $100. The presence at any time, on or about any such meter, wire or pipe of any device or pipes or wires resulting in the diversion of electric current, water or gas, as above defined or resulting in the prevention of the proper action or just registration of the meter or meters, as above set forth, shall constitute prima facie evidence of knowledge on the part of the person having custody and control of the room or place where such device or pipe or wire is of the existence thereof, and the effect thereof and shall further constitute prima facie evidence of intention on the part of such person to defraud and shall bring such person prima facie within the scope, meaning and penalties of this article.

Utah Compiled Laws of 1917

Larceny

Sec. 8300.—Every person who, with intent to injure or defraud, makes or causes to be made any pipe, tube or other instrument, and connects the same, or causes it to be connected, with any main, service pipe or other pipe used for conducting or supplying any artificial or natural gas, in such manner as to supply such gas to any burner or orifice, by or at which such gas is consumed, around or without passing through the meter provided for the measuring and registering the quantity consumed, or in any other manner so as to evade payment therefor, and every person who, with like intent, injures or alters any gas meter, or obstructs its action is guilty of a misdemeanor.

Sec. 8301.—Every person who, with intent to injure or defraud, makes or causes to be made any connection by wire or other instrument with any cable or wire used for conducting or supplying electricity for power, lighting, heating or other purposes to any burner or orifice by or at which such electricity is used or consumed for lighting, heating, power or any other purpose, around or without passing through the meter provided for measuring and registering the quantity used or consumed, or in any other manner, so as to evade payment therefor, and every person who, with like intent, injures or alters any electric meter, or obstructs its action, is guilty of a misdemeanor.

Sec. 7905.—Except in cases where a different punishment is prescribed by law, every offence declared to be a misdemeanor is punishable by imprisonment in a county jail not exceeding six months, or by a fine in any sum less than $300, or by both. In all cases, where a corporation is convicted of an offence for the commission of which a natural person would be punishable as for a misdemeanor, and there is no other punishment prescribed by law, such corporation is punishable by a fine not exceeding $1,000.

In Morrison Pie Co. vs. Utah Power & Light Co., P. U. R. 1921 C. 191, it was held by the Utah Public Utilities Commission to quote the headnote:

A consumer whose meter had been so tampered with as to result in the registration of less current than actually consumed, was ordered to install such protection as should be necessary to prevent interference, upon penalty of discontinuance of service.

Vermont General Laws of 1917

Trespasses and Malicious Injuries

Sec. 6972.—A person who taps gas pipes with intent to take gas therefrom, or who connects pipes with such gas pipes so that gas may be used without passing through the meters for measurement, or who knowingly burns gas without measurement by gas meters, without the consent of the owner, shall be imprisoned not more than one year, or fined not more than $100, or both; and the owner of the gas may recover of the person so unlawfully tapping or connecting such pipes or using gas the actual damages, with costs, in an action of tort.

Sec. 6973.—A person who wilfully commits or causes to be committed an act with intent to injure a machine, apparatus or structure appertaining to the works of a person, firm, association or corporation engaged in manufacturing, selling or distributing electrical energy in this State, or whereby such works may be stopped, obstructed or injured, or who taps an electrical line of a person, firm, association or corporation so that electricity can be taken therefrom, or knowingly uses electricity taken from such line without the consent of such person, firm, association or corporation, shall be imprisoned not more than two years, or fined not more than $300, or both; and such person shall also be liable to such person, firm, association or corporation or to anyone injured for actual damages, with full costs, in an action of tort. Justices shall have concurrent jurisdiction with county, municipal and city courts of offences arising under this section. (Amended L. 1927, Act No. 129.)

Sec. 6974.—A person, other than an authorized agent or employee acting for the owner, manufacturer or operator thereof, who maliciously opens, closes, breaks into or in any manner adjusts or interferes with a meter, or other regulating or measuring device or appliance attached to or connected with wires, pipe lines, mains, service pipes or house pipes owned or used by a manufacturer or furnisher of electricity, gas or water, shall be imprisoned not more than three months or fined not more than $100, or both.

Virginia Code of 1924

Offenses Against Property

Sec. 4478.—Any person who shall unlawfully injure or destroy, or having the right to prevent it, shall permit to be injured or destroyed any meter, pipe, conduit, wire, line, post, lamp or other apparatus belonging to a city or town or to a company engaged in the manufacture or sale of electricity or gas for lighting or power purposes, or who shall unlawfully prevent an electric or gas meter from duly registering the quantity of electricity or gas supplied, or in any way unlawfully interfere with its proper action or just registration, or who shall without the consent of such company or city or town unlawfully divert any electric current from any wire of such company or city or town, or who shall otherwise unlawfully use or cause to be used without the consent of such company or city or town any electricity or gas manufactured or distributed by such company or city or town, shall be deemed guilty of a misdemeanor. (1897-8, p. 254.)

Sec. 4782.—A misdemeanor, for which no punishment or no maximum punishment is prescribed by statute, shall be punished by fine not exceeding $500 or confinement in jail not exceeding twelve months, or both, in the discretion of the jury or of the justice, or of the court trying the case without a jury. (Code 1887, Sec. 3902; 1902-3-4, p. 784.)

Washington (Remington's) Compiled Statutes 1922

Crime Against Property

Sec. 2657.—Every person who, with intent to injure or defraud, shall—

(1) Break or deface the seal of any gas, electric, steam or water meter; or,

(2) Obstruct, alter, injure or prevent the action of any meter or other instrument used to register or measure the quantity of gas, electricity, steam or water supplied to a consumer thereof, or,

(3) Make any connection by means of a wire, pipe, conduit or otherwise with any wire, main or pipe used for the delivery of gas, electricity, steam or water to a consumer thereof, in such manner as to take gas, electricity, steam or water from said wire, main or pipe without its passage through the meter or other instrument provided for registering the amount or quantity consumed; or use any gas, electricity, steam or water so obtained; or,

(4) make any connection or reconnection with such wire, main or pipe, or turn on or off, or in any manner interfere with any valve, stop-cock or other appliance connected therewith; or,

(5) Prevent by the erection of any device or construction, or by any other means, free access to any meter or other instrument for registering or measuring the amount of gas,

electricity, steam or water consumed, or interfere with, obstruct or prevent, by any means, the reading or inspection of such meter or instrument, by the person, company or corporation owning the same; or,

(6) Take or use any water from any irrigation flume, ditch or lateral, without the consent of the owners thereof, or open, close or interfere with any gate connected therewith;

Shall be guilty of a misdemeanor. (L. '09, p. 1018, Sec. 405.)

Sec. 2266—Every person convicted of a misdemeanor for which no punishment is prescribed by any statute in force at the time of conviction and sentence, shall be punished by imprisonment in the county jail for not more than ninety days, or by a fine of not more than $250. (L. '09, p. 894, Sec. 14.)

West Virginia Acts of 1923

Chapter 65

Sec. 1.—Every person who, with intent to injure or defraud, procures, makes, or causes to be made, any pipe, tube, wire, or other conductor of gas, water, or electric energy, and connects the same, or causes it to be connected, with any main, service pipe or other pipe for conducting or supplying gas, or water, or any wires or other conductor of electric energy, in such manner as to supply gas, water, or electric energy to any lamp, motor, burner, orifice, or any other device, by or at which gas, water or electric energy is consumed, around or without passing through the meter provided for the measuring and registering of the quantity of gas, water or electric energy consumed, or in any other manner so as to evade payment therefor, and every person who, with like intent, injures or alters any gas, water or electric meter, or obstructs its action, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by imprisonment in the county jail not exceeding twelve months, or by a fine not exceeding $1,000, or both, at the discretion of the court.

Sec. 2.—Every person who, with intent to injure or defraud, connects, or causes to be connected, any pipe, tube, wire, electrical conductor or other instrument with any main service pipe, or other pipe or conduit or flume for conducting water, or with any main service pipe, or other pipe or conduit for conducting gas, or with any main, service wires or other electric conductor, used for the purpose of conducting electric energy for light, heat or motive services, for the purpose of taking therefrom, water, gas or electric energy, without the knowledge of the owner thereof and with intent to evade payment therefor, shall be guilty of a misdemeanor, and, upon conviction thereof, shall be punished by imprisonment in the county jail not exceeding twelve months, or by a fine not exceeding $1,000, or both, at the discretion of the court. (Barnes' Annotated Statutes, Supp. 1925, c. 145, Sec. 37.)

Wisconsin Statutes 1927

Offenses Against Property

Sec. 343.33 (2).—Or any person who wilfully, with intent to cheat or defraud the buyer or seller of electric current, gas, water, or steam, shall make or cause to be made or aid in the making of any electric conductor, gas pipe, water pipe, steam pipe, or other instrument or contrivance, or any connection as to conduct or supply or intended to conduct or supply electric current, gas, water, or steam to any lamp or motor or machine or burner or orifice or appliance from which such electricity, gas, water, or steam may be consumed or utilized, without passing through or being registered by a meter; or any person who shall wilfully use a false meter for the measurement of electric current, gas, water, or steam in the buying or selling of the same; or who shall wilfully obstruct or interfere with the working of any meter used for such purposes, so as to cause or be intended to cause a false registration of the amount of electric current, water, gas, or steam consumed with the intent to cheat or defraud the seller or buyer of such electric current, gas, water, or steam, shall be punished by imprisonment in the county jail not more than one year or by a fine not exceeding $500; but in case the amount of damages occasioned by such cheat or fraud shall not exceed $20, he shall be punished by imprisonment in the county jail not more than three months or by fine not exceeding $100; and in computing the amount of damages occasioned, the value of such electric current, water, gas, or steam shall be the regular current price therefor, charged to the consumer by the seller thereof.

In Minkel vs. Wisconsin Gas & Electric Co., P. U. R. 1923 E, 732, the Wisconsin Railroad Commission held that it was not the proper tribunal to decide whether or not a gas consumer had interfered with the registration of a meter in violation of a penal statute, and, until declared otherwise by proper court proceedings, consumers must be presumed to be innocent of wrongdoing.

Wyoming Compiled Statutes Annotated 1920

Crimes Against Property

Sec. 7114.—Any person who connects any pipe or other conduit, device or contrivance with any gas main or lateral supply pipe, supplying or intended to supply gas to any house, store or other building, without the knowledge and consent of any person or corporation owning said gas main or lateral supply pipe, in such manner that any portion of such gas may be transmitted or supplied to any lamp burner, heating apparatus, engine or other instrument or thing by or at which gas is consumed or used, shall be deemed guilty of a misdemeanor and punished as provided in Sec. 7117 hereof. (L. 1911, c. 55, Sec. 1.)

Sec. 7115.—Any person who connects or changes any pipe or other conduit, device or contrivance with any gas main or lateral supply pipe, supplying or intended to supply gas to any house, store or other building, without the knowledge and consent of any person or corporation owning said gas main, or lateral supply pipe, in such manner that any portion of such gas may be transmitted or supplied to any lamp burner, heating apparatus, engine or other instrument or thing by or at which gas is consumed or used, around or without passing through the meter provided for measuring or registering the amount or quantity of gas passing through it, shall be deemed guilty of a misdemeanor and punished as provided in Sec. 7117 hereof. (L. 1911, c. 55, Sec. 2.)

Sec. 7116.—Any person who wilfully injures, alters, or by any instrument, device or contrivance in any manner interferes with or destroys the action or operation of any meter for measuring gas, or of the amount or quantity of gas passing through it without the knowledge or consent of the person or corporation owning the same, shall be deemed guilty of a misdemeanor and punished as provided in Sec. 7117 hereof. (L. 1911, c. 55, Sec. 3.)

Sec. 7117.—Any person convicted of a violation of any of the provisions of Sec. 7114 to 7116 shall be punished for each offence by a fine of not less than $50 nor more than $300, or by imprisonment in the county jail for a period of not less than thirty days or more than ninety days, or by both such fine and imprisonment. (L. 1911, c. 55, Sec. 4.)

Sec. 7118—Any person who connects or changes any wire, cord, socket, motor or other instrument, device or contrivance, with any wire transmitting or supplying, or intended to transmit or supply electricity to any house, store or other building, without the knowledge and consent of the person or corporation owning said wire, in such manner that any portion of such electricity may be transmitted or supplied to any globe, lamp, heating apparatus or other instrument by or at which electricity is consumed, shall be deemed guilty of a misdemeanor and punished as provided in Sec. 7121 hereof. (L. 1911, c. 59, Sec. 1.)

Sec. 7119.—Any person who connects or changes any wire, cord, socket, motor or other instrument, device or contrivance with any wire, transmitting or supplying or intended to transmit or supply electricity to any house, store or other building, without the knowledge and consent of the person or corporation owning said wire, in such manner as to transmit or supply any such electricity to any globe, lamp, heating apparatus or other instrument by or at which electricity is consumed, around or without passing through the meter provided for measuring or registering the amount or quantity of electricity passing through it, shall be deemed guilty of a misdemeanor and punished as provided in Sec. 7121 hereof. (L. 1911, c. 59, Sec. 2.)

Sec. 7120.—Any person who wilfully injures, alters or by any instrument, device or contrivance in any manner interferes with or obstructs the action or operation of any meter for measuring electricity, or the amount or quantity of electricity passing though it without the knowledge and consent of the person or corporation owning said meter, shall be deemed guilty of a misdemeanor and punished as provided in Sec. 7121 hereof. (L. 1911, c. 59, Sec. 3.)

Sec. 7121.—Any person convicted of a violation of any of the provisions of Sec. 7118 to 7120 shall be punished for each offence by a fine of not less than $50 nor more than $300, or by imprisonment in the county jail for a period of not less than thirty days, or more than ninety days, or by both such fine and imprisonment. (L. 1911, c. 59, Sec. 4.)

LOW TENSION METERING INSTALLATIONS

This serial report of the Meter Committee, Engineering National Section, N. E. L. A., presents the modern trend of low tension metering installation practice. Various schemes are discussed, and their advantages and disadvantages are pointed out.

General

The trend of modern installation practice is to provide metal inclosures for all service conductors and metering equipment between the electric company's mains and the load side of the meter. This is generally accomplished by inclosing the service wires in metal conduit installed so as to eliminate condulets and pull boxes, and inclosing the main switch, fuses, meter terminals, test facilities and connections in metal boxes or cabinets. The advantages of metal inclosures have become more generally recognized as they minimize accidental damage, make tampering more difficult, serve as a safety measure, and aid in the standardization of meter installations. These features have been determining factors in bringing about a more extended use of metal-inclosed equipment, particularly in the larger companies.

The use of service-entrance meter cabinets embodying the service switch, fuses, test facilities and meter mounting actually present an economic advantage in that no coordination of effort is required between the electrical contractor and the utility when making an electrical installation. The cabinet combines all the necessary component parts of the old style open wire installation.

In the initial development of service-entrance meter cabinets, one of the most difficult problems was to provide simple and economical devices for fitting meters of diversified types and shapes. Metal fittings and inclosures suitable for top-connected meters in general were not applicable to those having side connections, and metal cabinets made for the latter were not suitable for bottom-connected meters. These conditions contributed to the complications encountered in the design and production of cabinets of simple construction for fitting the various makes, types and kinds of meters. A large variety of ingenious adapting devices were consequently developed, many of which were protected by patents covering particular designs and methods of construction.

Developments in metering practice led to a general demand for a bottom-connected single-phase meter, and a result of its production was the elimination of the necessity for a large number of the adapting devices which have since become obsolete. This reduction in the number and kinds of fittings and devices to be manufactured aided in the progress of standardization.

Location of Service Fuses

Simplification in installation practice and improvements in methods of connecting small installations, especially those for residences, necessitated some modifications in service-entrance meter cabinet designs. In accordance with the practice of some utilities the service fuses must be under seal, inaccessible to the customer but accessible to authorized employees. Other utilities require cabinet construction which will permit the use of main fuses accessible to the customer. It is generally conceded that the most desirable construction does not permit the customer to have access to live parts on the service side of the meter.

Service fuses accessible to the customer may be arranged in several ways to comply with the requirements of utilities operating under different rulings of regulatory bodies or agencies. An acceptable design of installation embodying this feature consists of connecting the fuses ahead of the meter and arranging the service switch so as to entirely disconnect the fuses from the line and load, at which time the fuses become accessible to the customer. This method of connection protects the customer against contact with live parts and wires. The use of six-terminal, three-wire meters having the potential circuit connected to the line ahead of the fuses on three-wire circuits is a protection against tampering when this method of connection is employed.

Another installation practice is to connect the fuses, arranged so as to be open or in a box, ahead of the meter, making them accessible to the customer at all times. This arrangement, however, nullifies the chief advantage of the use of inclosed protected service to the meter and meter connection cabinet and makes tampering easier on account of the accessibility of live parts on the service side of the meter.

An alternative, where permitted by the National Electric Code and by local inspection authorities, is the use of accessible fuses on the load side of the meter only, using on the service side of the meter a sealed and inclosed switch which may be operated externally. With this method of connection there would be no advantage in the use of six-terminal three-wire meters, as the meter is connected ahead of the fuses. Protection to testers against possible short circuits may be provided by the use of fuses in the test leads.

In one arrangement of this nature the fuses are eliminated entirely from the service-entrance meter cabinet, and only the service switch is placed therein. The customer's fuses serve as a protection in case of overloads or short circuits.

Service-Entrance Cabinets

Thought and consideration has been given to the question of the elimination of duplicate equipment installed in conjunction with service-entrance cab-

---

Publication No. 289-39, Serial Report, Meter Committee.

inets. This applies to cases where, in addition to the switch of the service-entrance cabinet, the customer provides a house switch and fuses, or in group installations, where an additional main switch is installed. Simplification in practice has been effected to some extent by regulatory rules which have permitted under certain conditions the elimination of the main service switch. The use of protective devices such as circuit breakers may result in changes in practice which may be somewhat different from the methods employed at present.

The simplification of service-entrance cabinet equipment has also resulted from the universal elimination of the neutral fuse and its accompanying switch blade. Where the neutral is grounded practically all cabinets now provide one fuse and one blade for 100 to 125-volt two-wire meters, and two fuses and two blades for three-wire circuits with a neutral strap or suitable means for disconnecting the neutral wire.

Standardization of Bases for Single-Phase Meters

The Meter Committee realized that much could be accomplished to reduce the diversity of requirements for meter cabinets by effecting such standardization in meter design, as base dimensions, terminal chamber construction and connections, as this would permit the use of the different kinds of meters interchangeably with a simply constructed service-entrance meter cabinet equipment.

With this in view, the committee, cooperating with the meter manufacturers, standardized the bases for single-phase meters of 5 to 25-ampere rating (about 85 per cent of the total number of meters manufactured) by providing a projection on the bottom of the meter base to fit an adapter opening having dimensions of 3 11/16 in. × 1 13/32 in. The different makes of meters are now available in this design which will permit the use of a single adapter opening for 5 to 25-ampere single-phase meters.

A similar development has been accomplished with 50 to 75-ampere meters, and meters of these ratings with a standardized base projection to fit an adapter opening having the dimensions of 4½ in. × 1 23/32 in. are now in production.

Polyphase Meters

The use of meter cabinets for installations of polyphase side-connected meters has been somewhat retarded on account of the necessity for the use of complicated adapting devices. With the collaboration of the meter manufacturers, the bottom-connected polyphase meter which represents a more difficult development has been produced for the simplification of this problem. Bottom-connected polyphase meters of ratings up to 75 amperes having terminal chamber dimensions of 6¾ in. × 2 3/16 in. (including the terminal chamber cover) will be available in the near future.

Need for Further Standardization

The improvements in meter construction, standardization of parts, and the progress in metering methods have made possible many modifications which have simplified the production of service-entrance equipment. It is, however, realized that there are many variations in the design and construction of component parts of the equipment which might be eliminated should further standardization be effected. These include such details as knockouts, endwalls, thickness of metal, finish, wiring space, size of switch parts, test facilities, provision for grounding, sequence of connections and other variants.

Small Capacity Circuit Breakers

The use of small capacity circuit breakers has been advocated in place of fuses. They possess the advantage of providing a simple method for the customer to restore service to any part of the installation without the necessity of replacing fuses, or calling upon the company's service maintenance department, or some other agency. The use of these breakers in lieu of fuses in the house circuits has not, however, been at all general. Such general usage would unquestionably be an incentive to the development of their use in service-entrance cabinets. The service-entrance meter cabinet requirements in connection with circuit breakers include simplicity of design, reliability of operation, the possibility of sealing, an arrangement which makes live parts of the service inaccessible to the customer, reasonably low first cost, and the necessity of very little maintenance. It is also necessary, for this kind of service, to provide automatic operation in case the breaker is closed against a short circuit.

Development work along these lines is in progress by manufacturers; and some member companies, who are conducting investigations, have sample installations under observation. It appears probable that there will be some interesting developments in service equipment along the lines indicated. The committee is making a further study of this subject and will present the results as soon as progress warrants.

Requirements of Service-Entrance Cabinets

In general, service-entrance cabinets should be designed so as to include the externally operated fused switch to meet the requirements of the National Board of Fire Underwriters, and should provide a means in the interests of economy for the conjoint assembly with the meter so that none of the connections are exposed and accessible when the meter is installed and the cabinet is sealed. Such an assembly can include, at no great expense, for the mutual advantage of all interested parties, simple, adequate test connections. The sequence of connection of the component parts, however, may vary with individual requirements, and in some cases municipal or other requirements may introduce variations in arrangement and design.

The policy affecting the installing of service-entrance cabinets varies. In some cases these cabinets are furnished and installed by the utility, in other cases the customer supplies and installs the cabinet and the utility only mounts and connects the meter, and in some instances the company supplies the cabinet to the contractor for installation.

Service-entrance cabinets differ in that, some provide for the mounting of the meter on the metal back plate of the cabinet, while in other cases the meter is installed on a wooden board which also supports the cabinet. In the former type the metal back plate usually provides for the mounting of various makes and types of meters. The meter committee has cooperated with the manufacturers, by providing for the retention of existing spacings of mounting holes wherever possible, for modifications in design and new types of meters.

The sizes of cabinets is governed by various conditions. In general, it is desirable to provide sufficient space so that the test connections may be made safely and conveniently. It is also desirable to provide ample space so that main service conductors of relatively large size may be carried through a bank of cabinets with provision for making taps for the individual services.

It is recognized that in view of the numerous variations in design introduced by manufacturers in order to adapt their respective products to different requirements, it is difficult at this time to standardize on cabinets of specific sizes and designs, for metering installations of all sizes and kinds required for the wide range of a-c. and d-c. services of different classes, as supplied to large and small customers under various contract conditions.

It appears, however, that some specifications as to the general requirements which the 30-ampere service equipment should fulfill would be of interest and value, especially to those who have not had an opportunity to closely follow the developments.

The meter committee is making a further study of the requirements of member companies and the methods employed, with a view of determining the factors that effect uniform practice, and of ascertaining what suggestions can be made to further standardize service-entrance equipment.

Suggested Specifications for Service-Entrance Meter Cabinets

The suggested specifications given below apply to service-entrance meter cabinets used at the service entrance on the customer's premises, when such service is supplied from the lines of public utility companies, and are not intended to apply to meter cabinets for other purposes or for special applications.

Classification

(1) Service-entrance meter cabinets may be considered in two general classes, viz.:

(a) Those in which service fuses are under seal and are accessible only to authorized employees.

(b) Those in which the service fuses are accessible to the customer.

(2) Either class may be of the "all metal" type in which the meter itself is bolted to the metal base plate; or cabinets which inclose only the fuse, switch and test device, and above which the meter is mounted by being attached to a wooden board which also supports the cabinet.

(3) Meters may be applied to the cabinets so that the terminal chamber of the meter extends into the cabinet, or so that the terminal chambers of the meters abut the cabinet.

General Requirements

(4) Cabinets of the 30-ampere rating intended for use with 5 to 25-ampere single-phase alternating-current meters (installed so that the terminal chambers of the meters abut the adapter of *the cabinet*) should be provided with the standardized opening of 3 11/16 in. × 1 13/32 in. with the two outer corners rounded to a radius of ⅛ in.

(5) Cabinets for single-phase alternating-current meters of 25, 50 and 75-ampere ratings arranged so that the meter terminal chamber enters the cabinet, should be provided with an opening of 4½ in. × 1 23/32 in.

(6) Cabinets provided for bottom-connected polyphase meters and designed for the terminal chamber of the meter to enter the cabinet should have an adapter opening of 6⅞ in. × 2 5/16 in.

(7) Cabinets provided for bottom-connected polyphase meters and designed for the bottom of the terminal chamber to abut the adapter should have an adapter opening of 6⅝ in. × 2 1/16 in.

(8) The adapter openings of new cabinets should be closed by a shutter or a blank adapter. When blank adapters or shutters are separate from the meter adapter, the meter adapter should be supplied with the cabinets.

(9) Service-entrance meter cabinets designed for use with the meters of public utilities should be confined to the meter control and protective equipment. The addition of branch circuit cutouts or other devices may not be desirable.

Sizes

(10) Service-entrance meter cabinets should be of such a size as to provide adequate space for testing.

(11) Service-entrance meter cabinets must provide space for carrying service conductors through the cabinet when such cabinets are intended mainly for banked installations.

Covers

(12) Covers should be hinged and so arranged that when open they will not obscure the meters or interfere with test wirings or connections.

Arrangement of Cabinets

(13) Where consideration has been given to the use of cabinets, either as a service-entrance meter cabinet or as a service-entrance cabinet in a banked installation with knockouts or troughs, they should be arranged so that a centrally located cabinet in a group installation may be removed without the necessity of dismantling adjacent cabinets.

(14) Service-entrance meter cabinets may be adaptable to banked or grouped installations. This may be done either by means of conduit connections or troughs.

(15) The test device, the service switch, and the fuses should be arranged so that test links, connecting screws, etc., used for testing or for purposes of installation are easily accessible either when the cabinet is used alone or as a unit in a banked installation.

Sealing

(16) The cabinets should be designed so that they may be opened by authorized employees without interrupting the circuit, but the method of sealing should be such that the cover cannot be opened without breaking the seal.

(17) Service switches should be arranged so that they may be sealed externally in the open position.

(18) Sealing methods should be such that either the conventional types of padlock seal, strip metal seal, or lead button and wire seal may be applied to properly lock the cabinet cover in the full closed position.

Testing Facilities

(19) Test devices must provide facilities for readily bridging the meter current coils.

(20) Adequate provision should be made for attaching the connections required for service meter testing to the test device.

(21) Test devices should be constructed so as to minimize the possibility of corrosion in service.

(22) A diagram of connections showing the internal and external connections of the test device should be provided in each cabinet.

(23) The test device for three-wire and polyphase meters should make provision for the series connection of the current elements for test purposes.

Current Carrying Capacity

(24) Current carrying parts should be designed so that their temperature rise will not exceed that permitted by the standard specifications of the Underwriters' Laboratories, when carrying continuously the maximum current permitted by the largest fuse which may be inserted in the cabinet. Heating tests, however, should be made with fuses or equivalent resistances in place.

Fuses and Circuit Breakers

(25) Where fuses are accessible to the customer, the design should be arranged so that the fuse receptacle is disconnected from the source of supply when the fuses are accessible for replacement.

(26) Cabinets for two-wire 115-volt meters should be equipped with one fuse, with proper provision for connecting the unfused grounded service wire to the corresponding load wire.

(27) Cabinets for three-wire meters, for single-phase or open-star connections should be equipped with two fuses, with provision for connecting the neutral load and service wires without fuses. Provision should be made for connecting the individual potential leads of meters with independent potential circuits ahead of the fuses without disturbing any of the current-carrying connections.

(28) Cabinets for two-phase three-wire grounded neutral systems should be equipped with two fuses with provision for connecting the neutral load and service wires without fuses.

(29) Cabinets for two-phase five-wire meters on grounded neutral systems should be equipped with four fuses, with provision for connecting the neutral load and service wires without fuses.

(30) Cabinets for three-phase three-wire delta-connected systems should be equipped with three fuses.

(31) Cabinets for three-phase four-wire meters on grounded neutral systems should be equipped with three fuses, with provision for connecting the neutral load and service wires without fuses.

(32) When circuit breakers are employed in place of fuses, their application should be in accordance with clauses 26 to 31 inclusive.

(33) Circuit breakers approved for use in service-entrance cabinets should be provided with facilities for sealing the current setting.

(34) Circuit breakers should be designed so as to be in accord with the complete specifications of the Underwriters' Laboratories.

Switches

(35) Service switches installed within meter cabinets should be externally operated.

(36) When the operating handle is located at the side of the cabinet, the design should be such that the switch is closed when the handle is in the upper extremity of its travel.

(37) Rotary switches should be so arranged that the switch is closed when the handle is in the upper extremity of its travel.

(38) Switch blades must be provided for all ungrounded lines. This will necessitate that the switch open all wires for which fuses are provided in accordance with paragraphs 26 to 31 inclusive.

(39) Switches should be arranged so that they may be sealed in either the open or closed positions.

(40) The details of mechanical and electrical design should be in accordance with the Standard Specifications of the Underwriters' Laboratories covering externally operated switches, knife switches and cutout bases.

Finish

(41) Service-entrance meter cabinets should be protected against corrosion by galvanizing, sherardizing, or by the use of moisture-proof paint both inside and outside.

(42) The cabinets and their accessories should be designed so that the operating parts will not become corroded through disuse in the normal service to which meter cabinets may be subjected.

SUMMARY OF PUBLIC UTILITY COMMISSION RULES AND REGULATIONS FOR ELECTRICITY METERS

Rules and regulations for electricity meters have been adopted in twenty-one States and the District of Columbia. In order to show clearly the similarities and differences in the service rules so far adopted by State commissions, abstracts of these rules have been segregated under appropriate headings in this report.

An attempt has been made to place the abstract of each rule under the heading best describing the subject matter of the rule. It is believed that all the rules of each commission have been abstracted and included in this report. To determine what each State's rules are, it is necessary only to read under each heading the abstract of the rules for the State in question. If no abstract is given, no rule has been adopted.

The purpose of the report is, obviously, to acquaint individuals interested in meters with the rules in effect throughout the country. It is hoped that Meter Committee members and others interested in these rules may take the necessary steps to eliminate some of the existing differences, and that ultimately the rules in all the States may become standardized.

Primary Standards

Colorado

Rule 5, Rule 34-A—Each utility shall provide such meter laboratory, standard meters and other equipment acceptable to the Commission and sufficient to make all the tests prescribed. Utilities with authorized standard laboratory may certify their own reference standards and those of other utilities.

Connecticut

Rule E-12, Rule 2—Each utility must provide and maintain such standards and portable testing instruments as may be deemed necessary and approved by the Commission.

Rule E-12-d—Any standardizing laboratory whose instruments and methods are approved by the Commission may certify portable and reference standards.

District of Columbia

Rule 3—Each electrical corporation shall provide and maintain suitable apparatus and facilities for testing the accuracy of meters.

Illinois

Rule 8-a—Each utility shall provide and maintain such meter laboratory and instruments as may be necessary to make the tests required by the Commission.

Indiana

Rule 11-b—Each utility shall maintain a standardizing laboratory. Each utility must provide and maintain such laboratory, standard meters and equipment as may be necessary to make all the tests required by the Commission.

Rule 11-a—If instruments and methods are approved by the Commission, the laboratory may certify the accuracy of its own meters and those of other utilities.

Maryland

Rule E-2—Each utility shall maintain and provide such meter testing facilities as are necessary to make all tests of its service meters.

Michigan

Rule 44—Each utility shall provide and properly maintain suitable primary standards to be used for checking reference standards.

Rule 41—If a utility is maintaining a laboratory, the Commission may authorize such utility to have power to test and certify meters of other utilities.

Missouri

Rule 35—Each utility may provide and maintain primary standards. If not, secondary or reference standards must be submitted to some testing laboratory of recognized standing at sufficiently frequent intervals.

Montana

Rule 27-a—Each utility with more than 250 meters in service shall maintain a standardizing laboratory equipped with standard meters, instruments and such facilities as are necessary to make tests required by the Commission.

New Hampshire

Rule 9—Each utility shall have available in proper working condition suitable standards for testing its meters and shall maintain these standards accurate within one-half of 1 per cent, or apply the proper corrections to each test.

New Jersey

Rule XIX-a—All utilities must provide and maintain such laboratory, meter testing shop, standards, instruments and such other facilities to make the test required by the Board.

Rule XIX-e—Any standardizing laboratory whose instruments and methods are approved by the Board may test and certify instruments and standards.

New York

Case No. 278-1921

Section 25—Each utility must provide and maintain suitable apparatus and facilities for testing and approving the accuracy of watt-hour meters.

Section 24—If a standardizing laboratory is maintained and approved by the Commission, it may certify meters and instruments for testing purposes.

North Dakota

Rule 11-b—Each utility, unless excused by the Commission, shall provide and maintain such laboratory standard meters and equipment as may be necessary to make the tests required.

Rule 11-a—If instruments and methods of a standardizing laboratory be approved by the Commission, such laboratory may certify meters and instruments for its own use and for other utilities.

Oklahoma

Rule 12-b—Each utility must provide and maintain such laboratory, standard meters and equipment as may be necessary to make the tests required by the Commission.

Publication No. 289-40, Serial Report, Meter Committee.

Rule 12-a—If instruments and methods are approved by the Commission, the laboratory may certify the accuracy of its own meters and those of other utilities.

Oregon

Rule 2-a—Each utility shall provide such laboratory, meter testing shop and other facilities as may be necessary to make the tests required by the Commission.

Pennsylvania

Rule XV—Each utility shall provide facilities approved by the Commission for testing its watt-hour meters, to include: test bench, one or more portable rotating standard watt-hour meters, a suitable check meter or meters mounted on test bench and such other equipment as required by the Commission.

South Carolina

Rule 13-a—Each utility shall, unless excused by the Commission, provide and maintain such laboratory, standard meters, instruments and facilities as may be necessary to make the test required by the Commission.

Washington

Rule E11-b—Each utility shall provide such meter laboratory, standard meters and other equipment and facilities for making the tests required by the Department.

Rule E11-a—Any standardizing laboratory whose instruments and methods are approved by the Department may certify meters and instruments for its own use and for other utilities. Utilities not maintaining standardizing laboratories may obtain authorization from the Department to have certification of meters made for them by any approved standardizing laboratory.

West Virginia

Rule 23-a—Each utility shall provide such laboratory, meter testing shop, instruments and equipment as may be necessary to determine the accuracy of its consumers' meters, unless relieved of such requirement by the Commission.

Rule 23-b—The minimum testing equipment shall be a portable rotating standard of sufficient capacity to test all service meters upon the utility's system.

Secondary Standards

Colorado

Rule 34-b—For testing accuracy of portable rotating standards and other portable standards each utility must provide suitable reference standards. Such reference standards may be of a service type of watt-hour meter if permanently mounted and used for no other purpose. Reference standards shall be checked once a year at an authorized laboratory.

Connecticut

Rule E-12-a—Reference standards shall be provided and maintained as deemed necessary and approved by the Commission.

Illinois

Rule 8-c—Each utility shall provide suitable instruments called reference standards for testing the accuracy of rotating standards and other working standards. For utilities with less than 500 meters in service a regular service type of meter may be used as a reference standard if placed permanently in a place free from vibration and other disturbing influences and used for no other purpose.

Reference standards shall be checked once a year in some approved laboratory.

Indiana

Rule 11-C—Each utility not excused by the Commission, shall provide and maintain reference standards to check the accuracy of portable standards. If the reference standard is of the service watt-hour meter type, it must be permanently mounted in the meter laboratory.

Reference standards of all kinds should be tested at least once a year in a standardizing laboratory.

Maryland

Rule E-2—Utilities shall provide and maintain suitable electrical meters and instruments to be used as reference standards for testing the accuracy of the portable working standards. They may be of service type watt-hour meter, if permanently mounted in the laboratory and used for nothing else.

Reference standards should be tested and adjusted each year by the Commission.

Michigan

Rule 43—Each utility shall provide and maintain suitable electrical instruments to be used as reference standards, permanently mounted in meter laboratory.

Rule 45-f—Reference standards used to check portable watt-hour meters shall be tested and certified at least once every 6 months in an approved meter testing laboratory. Each reference standard shall be accompanied by a certificate of accuracy.

Missouri

Rule 35—Each utility having more than 250 meters in service shall own and maintain approved secondary standards for calibrating working standards. Each standard shall be accompanied by its calibration card, and when calibration cards are superseded they shall be kept on file.

Montana

Rule 27-c—Each utility shall provide reference standards for testing working standards. Such reference standards may be of the service type, if permanently mounted and used for no other purpose than checking working standards.

Reference standards should be certified by some approved laboratory at least once a year.

New Jersey

Rule XIX-c—Every utility shall provide and maintain suitable instruments as reference standards for testing the accuracy of portable meters used for testing customers' service meters. Such standards may be service type watt-hour meters, if permanently mounted in the laboratory and used for no other purpose than checking working standards.

All reference standards may be tested, adjusted and sealed by the Board.

New York

Case No. 278—1921

Section 26—Each utility shall provide and maintain suitable indicating electrical instruments as reference standards, mounted in a permanent position.

Reference standards shall be certified once every two months by comparison with the standards of a standardizing laboratory, or the standards of the Commission, or by specific permission, with the standards of other laboratories.

North Dakota

Rule 11-c—Each utility shall provide and maintain reference standards for testing the accuracy of portable testing meters. Such reference standards may be service type meters.

Reference standards should be tested once a year.

Oklahoma

Rule 12-c—Each utility, not excused by the Commission, shall provide and maintain reference standards to check the accuracy of portable standards.

Utilities with less than 500 meters in service may use a service type watt-hour meter as reference standard.

Reference standards of all kinds should be tested at least once a year in a standardizing laboratory.

Oregon

Rule 20-a—Secondary standards of some approved type shall be owned and maintained by each utility having more than 250 electric meters in service.

Pennsylvania

Section XV-I—Reference standard or check meter shall be tested periodically and adjusted when necessary by a representative of the Commission at such place as it may direct. Such meter shall be sealed and date-tagged immediately after adjustment, and the utility shall be furnished with correction curve dated and signed.

2—Portable rotating standards shall be tested and adjusted periodically by a representative of the Commission at such place as it may direct. Correction curve properly dated and signed shall be furnished to the utility.

3—During interval between tests by the Commission the portable standards shall be compared with a check meter at least once each week for commutating type, and every two weeks for induction type. Complete records of checks shall be kept two years.

Washington

Rule E-11-c—Each utility shall provide and maintain suitable reference standards for testing the accuracy of portable watt-hour meters called rotating standards and other portable instruments used for testing service meters. Such standards may be service type watt-hour meters if permanently mounted in the meter laboratory of the utility and used for no other purpose than checking working rotating standards.

Reference standards shall be certified bv comparison with the standards of a standardizing laboratory approved by the Department.

West Virginia

Rule 23-c—A utility may or may not have secondary standards. When no regular secondary standards are maintained, the utility must have more than one portable rotating standard, and alternately they shall be sent to a suitable laboratory, at least once every three months, for checking and certification. One such standard should be kept as an office standard and not used for field work. The standards used for field work shall be checked against the office standard at least every two weeks.

Minimum requirement for checking portable rotating standards is to install in the shop of the utility a 5-ampere, single-phase watt-hour meter with potential coils like the potential coils of one of the rotating standards; such meter to be adjusted accurate within one-fourth of one per cent, with 3 amperes flowing in the current coil. This meter shall be certified at least once every year.

When the minimum requirement is in effect the portable rotating standards shall be checked against the standard meters once every two weeks.

Wisconsin

Rule 18—Secondary or reference standards should be owned by electric utilities having more than 250 meters in service. Reference standards should be tested at least once a year in a standardizing laboratory.

Working Standards

Colorado

Rule 34-b—Rotating standards shall be compared with reference standards every week for commutator type and every two weeks for induction type. One per cent plus or minus is limit for error unless accompanied by calibration card.

Portable indicating instruments shall be checked against reference standards every week. One per cent of full scale deflection is limit for error.

All portable standards shall be accompanied by calibration card; when superseded such cards shall be filed in office of utility.

Connecticut

Rule E-12-b—Portable rotating standards shall be compared with reference standards at least once each week for commutator types and once every two weeks for induction types. If such check shows error in excess of 2 per cent, the rotating standard shall be readjusted and certified in an approved laboratory. Each portable rotating standard shall at all times be accompanied by a certificate of correction.

Rule E-12-c—Portable indicating testing instruments shall be checked against reference standards at least once a week. If in error at zero, or more than 1 per cent at commonly used scale deflections, it shall be adjusted and certified in an approved laboratory before being used again.

District of Columbia

Rule 4—All working standards shall be tested for accuracy as often as is necessary, to insure their maintenance in proper condition. If not checked in the laboratory of the electrical corporation, working standards shall be tested in a properly equipped laboratory of recognized standing.

Each working standard shall at all times be accompanied by a certificate giving date on which it was last checked and the corrections to be applied. When superseded the certificate shall be kept on file in the office of the utility.

Illinois

Rule 8-d—When rotating standards are regularly used they shall be compared with the reference standards at least once each week, if of the commutator or mercury type, or at least once each two weeks, if of the induction type. For utilities having less than 500 meters in service a regular service type watt-hour meter may be used for checking working standards in the district where the tests are being made, provided comparisons are made at least once a month with the approved reference standards of the central testing station. If the rotating standard is in error by more than 1 per cent it shall be adjusted, if possible. In any case, the correction indicated by the calibration card (see Rule 8-g) shall be applied.

Rule 8-e—All working standards of the indicating type shall be compared with reference standards at least once a week. If found in error at zero, or more than 1 per cent in error at commonly used scale deflections, the instrument shall be adjusted, or the proper correction factor shall be applied.

Rule 8-f—Station meters shall be checked at least once a year.

Rule 8-g—Each working or reference standard shall be at all times accompanied by a calibration card. When superseded they shall be kept on file in the utility office.

Indiana

Rule 11-c—Rotating standards should be compared with reference standards once a week for commutator types, and every two weeks for induction types. The error should be less than 1 per cent plus or minus, unless calibration card accompanies rotating standard. Records of certification and calibrations shall be kept on file in the office of the utility.

Portable testing instruments, such as voltmeters, ammeters and wattmeters shall be checked with reference standards once a week when continually in use. Error shall be less than 1 per cent of full scale value at commonly used scale deflections, unless accompanied by calibration card.

Maryland

Rule E-2—Each utility shall provide and maintain suitable portable testing equipment for use as working standards.

Michigan

Rule 42—Each utility shall provide and properly maintain portable testing instruments and rotating standards as deemed necessary and satisfactory by the Commission for testing service meters, switchboard meters and other electrical instruments in use.

Rule 45-d—All portable indicating and recording meters, such as voltmeters, ammeters, wattmeters, frequency meters and power factor meters, shall be compared with reference standards at frequent intervals when regularly used. If such check shows any portable meter to have an error greater than 1 per cent at any load at which the meter is used, the meter shall be tested and adjusted with instruments of precision in an approved laboratory, unless the meter is accompanied by an accurate calibration chart, in which case an error of more than 1 per cent will be allowed.

Missouri

Rule 35—Each utility shall maintain suitable working standards of a rugged type for testing electric service meters. These working standards must be calibrated frequently to insure their accuracy. Each standard shall be accompanied by its calibration card, and when superseded they shall be kept on file at the office of the utility.

Montana

Rule 27-d—Rotating standards shall be compared with reference standards once a week for commutator types and every two weeks for induction types. Unless accompanied with calibration card, the meter shall be tested and certified if in error more than 1 per cent, plus or minus.

Rule 27-e—Portable testing instruments, such as voltmeters and ammeters, shall be checked against reference standards once a week; if the error is more than 1 per cent of full scale deflection at commonly used scale deflections, they shall be calibrated, unless accompanied by calibration card.

New Jersey

Rule XIX-b—Each utility shall provide portable meters of suitable range and type for testing service watt-hour meters, switchboard instruments and other electrical instruments in use.

Rule XIX-d and e—Rotating standards and all portable standards when in regular service shall be compared with reference standards at least once each week. They shall be accompanied by a certificate, or calibration card. When superseded these certificates shall be kept on file for one year in the office of the utility.

New York

Case No. 278—1921

Section 27—Portable rotating standards shall be compared with reference standards once each week for commutator types and once every two weeks for induction types. If such comparison shows error more than 1 per cent, plus or minus, at any load on which the standard will be used, it shall be adjusted and certified by comparison with reference standards in the company's own laboratory before again being used.

Each portable rotating standard shall have a certificate attached, signed by the proper authority, giving date when last certified, and company's or manufacturer's number. The accuracy shall be shown either as per cent accuracy of the portable standard or as the actual per cent correction to be applied at the various ampere loads at one or more voltages. When certificates are superseded they shall be filed for six months.

North Dakota

Rule 11-c—Rotating standards shall be compared with reference standards once a week for commutator types and once in two weeks for induction types. The error shall be less than 1 per cent, plus or minus. All rotating standards shall be accompanied by calibration cards. Records of calibration shall be kept on file in the office of the utility.

Portable indicating testing instruments when in regular use for testing purposes, shall be checked against reference standards once a week. Error shall be less than 1 per cent of full scale value at commonly used scale deflections, unless accompanied by calibration card.

Oklahoma

Rule 12-c—Rotating standards shall be compared with reference standards once a week for commutator types and every two weeks for induction types. The error shall be less than 1 per cent, plus or minus. The calibration card shall accompany rotating standards at all times. Records of certification and calibrations shall be kept on file in the office of the utility.

Portable testing instruments, such as voltmeters, ammeters and wattmeters, shall be checked with reference standards once a week when continually in use. Error shall be less than 1 per cent of full scale value at commonly used scale deflections, unless accompanied by calibration card.

Oregon

Rule 20-a—Every electric utility shall own suitable working standards for testing meters and shall maintain them correct within one-half of one per cent or apply proper corrections.

Pennsylvania

Rule XV-1—Reference standard or check meter shall be tested periodically and adjusted when necessary by a representative of the Commission at such place as it may direct. Meters shall be sealed and date-tagged immediately after adjustment. The utility shall be furnished with correction curve dated and signed.

2—Portable rotating standards shall be tested and adjusted periodically by a representative of the Commission at such place as it may direct. Correction curves properly dated and signed shall be furnished to each utility.

3—During interval between tests by the Commission, the portable standards shall be compared with a check meter at least once each week for commutator types, and every two weeks for induction types. Complete record of each check shall be kept two years.

South Carolina

Rule 13-b—All portable electrical testing instruments when in regular use for testing purposes shall be checked periodically against suitable reference standards to insure their accuracy.

Washington

Rule E-11—Rotating standards shall be compared with reference standards at least once a week for commutator types and once every two weeks for induction types. Error shall be less than 1 per cent, plus or minus, at any load at which standard will be used.

Portable standard indicating instruments shall be checked against reference standards at least once a week. Error should be less than 1 per cent of full scale deflection at commonly used scale deflections unless accompanied by a calibration card.

West Virginia

Rule 23-c—A utility may or may not have secondary standards. When no regular secondary standards are maintained the utility must have more than one portable rotating standard and alternately they shall be sent to a suitable laboratory at least once every three months for checking and certification. One such standard should be kept as an office standard and not used for field work. The standards used for field work shall be checked against the office standard at least every two weeks.

Minimum requirement for checking portable rotating standards is to install in the shop of the utility a 5-ampere, single-phase watt-hour meter with potential coils like the potential coils of one of the rotating standards; such meter shall be adjusted accurate within one-fourth of one per cent with 3 amperes flowing in the current coil. This meter shall be certified at least once every year.

When the minimum requirement is in effect the portable rotating standards shall be checked against the standard meters once every two weeks.

Wisconsin

Rule 18—Working standards should be owned by all utilities unless excused by the Commission.

Rule 19—Each utility furnishing metered electric service shall own suitable working standards and either maintain the standards correct within one-half of one per cent or apply the proper correction to all tests.

Direct-current rotating standards should be checked against the secondary standards daily; when the rotating standards are found in serious error, the day's work shall be repeated.

Initial Requirements for Meters

Colorado

Rule 35—Meter must have correct gear ratio, register constant, test constant and dial train. Meter must not creep.

Meter must not be in error more than 2 per cent plus or 3 per cent minus at 5 to 10 per cent rated meter capacity, or 2 per cent, plus or minus, at 60 to 100 per cent rated meter capacity.

Connecticut

Rule E-15—Meter must have correct register constant, test constant, gear ratio and dial train. Must not register on no load. Average error of meter shall not be in excess of 2 per cent.

At 50 per cent lagging power factor and 100 per cent rated current the meter error shall not be in excess of 2 per cent.

District of Columbia

Rule 2-G—Meter must not creep. The meter error shall be less than 1 per cent at 10 per cent of rated capacity of meter and less than 1 per cent at 60 to 100 per cent rated capacity of meter.

Illinois

Rule 10—Meter shall not make more than one complete revolution on no load. Meter must be mechanically perfect with correct constants.

Meters shall be adjusted so the error shall not exceed the amounts given: average error less than 2 per cent, for direct current and alternating current; error at full load less than 1 per cent, for direct current and alternating current; error at light load less than 4 per cent, for direct current and 3 per cent for alternating current.

Rule 13-c—Installation tests on watt-hour meters used on inductive loads shall consist either of tests approximating the customer's load at heavy and light load or of tests on non-inductive load at heavy and light load, provided a shop adjustment was previously made within 2 per cent at rated full load and 50 per cent lagging power factor.

Indiana

Rule 13-a and b—Meter shall not register at 110 per cent standard service voltage at no load. Meter shall be mechanically perfect and must have correct constants. Initial adjustment must be made so that the average error is not over plus or minus 2 per cent, while the error at heavy load is not over plus or minus 1 per cent and the error at light load is not over plus or minus 4 per cent.

Rule 13-c—At 50 per cent power factor and full rated current the meter error shall not be more than 2 per cent.

Maryland

Rule 4-a—Meter shall not creep under commercial range of voltage. Meter shall be mechanically right with correct ratio and constants. Meter error shall be less than 1 per cent. No meter shall be placed in service unless its accuracy has been established and marked with the seal of the Commission.

Michigan

Rule 27—Meter shall not register at no load when applied voltage is less than 110 per cent of standard voltage.

Rule 28—Meter shall be mechanically perfect and have proper constants. The average error shall be not over 2 per cent, plus or minus, while the light load error shall not be over 3 per cent, plus or minus. The heavy load error shall not be over 1 per cent, plus or minus.

Rule 26—At 50 per cent power factor and 100 per cent rated full load current meter error shall not be more than 2 per cent on meters which will or may be used on inductive load circuits.

Missouri

Rule 30—Meter shall have proper constants and dial trains and be mechanically perfect. Meter shall not creep at no load under maximum service voltage.

Rule 29—Each meter shall be adjusted as accurately as practicable on the following loads:

5 to 10 per cent rated capacity of meter.
50 per cent rated capacity of meter.
100 per cent rated capacity of meter.

Where the normal load under which meter operates is from 60 to 100 per cent of rated meter capacity, an equivalent test load may be substituted for the 50 and 100 per cent rated capacity loads.

Any meter operating on inductive load should be tested under the approximate P.F. condition at which it operates.

Where necessary to adjust a meter fast at light or heavy load for correct registration at normal load or to correct for inductive load, such fast adjustments should not exceed 2 per cent.

Montana

Rule 22—Meter shall not register at 110 per cent standard service voltage at no load. The allowable average error shall be less than 2 per cent, plus or minus. The error shall be less than 1 per cent, plus or minus, at heavy load, and less than 4 per cent, plus or minus, at light load.

Error shall be less than 2 per cent at power factor conditions approximating the power factor of the connected load.

New Hampshire

Rule 2—Meter shall not creep and shall have correct gear ratio, register constant, test constant and dial train.

Meter shall not be in error more than 4 per cent at light, normal and heavy loads.

New Jersey

Rule XXI—Meter shall not register on no load.

New York

P. S. Comm. Law, 1921, *Section* 67, *Subdivision* 3

No corporation, person, or municipality shall furnish, set or put in use any electric meter the type of which shall not have been approved by the Commission.

Case No. 278

Section 7—Each meter shall be tested and adjusted within the limits specified in Section 22, before installation or within 60 days after installation. Each direct-current watt-hour meter shall be tested and adjusted within 60 days after installation.

No reports of these tests need be filed, and they will not be considered as periodic, office or complaint tests.

Section 22—Meters shall be adjusted so as to register with an error of not more than 1 per cent at 10 and 100 per cent capacity (light and full load).

Section 23—A meter shall be considered as creeping when, on no load, the disk rotates 1 revolution in 5 minutes or less. This observation shall be made with all house wires removed from the meter. All meters in service shall be left without creep.

North Dakota

Rule 13—Meter shall not register at 110 per cent standard service voltage at no load. Meter shall be mechanically perfect and have correct constants. The average error shall be not more than 2 per cent, plus or minus. The error at heavy load shall be not over 1 per cent, plus or minus, and at light load it shall be not over 4 per cent, plus or minus.

A-C. service meters which are to be used on circuits supplying inductive load shall be tested, before installing, at 100 per cent of rated current and 50 per cent lagging power factor.

Oklahoma

Rule 13—Meter shall not creep. Meter shall have correct register constants, test constants, gear ratio, dial train and be mechanically perfect. The average error shall be not more than 2 per cent. The light load error shall be not more than plus 2 per cent or minus 4 per cent, while at heavy load the error shall be not more than plus or minus 2 per cent.

Rule 16-B—At 50 per cent power factor and full rated current the error shall be less than 2 per cent.

Oregon

Rule 24-a—Meter shall not register at no load nor have incorrect register constant, test constant, gear ratio or dial train.

Pennsylvania

Rule XI—Meter shall not register at no load when voltage is less than 110 per cent of standard service voltage. Meter must have proper constants, be mechanically perfect, and its error must be not more than 4 per cent.

Rule XIX—Error shall be less than 4 per cent, plus or minus, at 50 per cent lagging power factor.

South Carolina

Rule 15—Meter shall not creep at 110 per cent of standard service voltage at no load. Meter shall be mechanically perfect with correct constants and have errors less than 1 per cent, plus or minus, at full load, 2 per cent, plus or minus, at light load, with an average less than 2 per cent, plus or minus.

Washington

Rule E-12—Meter shall have proper register constant, test constant, gear ratio and dial train, and shall not register at no load.

Error shall not be over 4 per cent, plus or minus, at 10 per cent and 100 per cent capacity of meter. Meter shall be adjusted as nearly 100 per cent as possible.

Rule E-9—Error shall be less than 2 per cent at 50 per cent power factor and 100 per cent rated current.

West Virginia

Rule 24-a—Meter shall be mechanically right without creep. The error shall be less than 1 per cent at light and normal loads.

Wisconsin

Rule 14—Meter shall not creep.

Rule 15—Meter shall have correct register constant, test constant, gear ratio and dial train, and its error shall be less than 4 per cent between light and full connected loads.

Requirements for Meters with Auxiliary Apparatus

Colorado

Rule 35-d—Meters installed with instrument transformers or shunts shall be tested jointly with such transformers or shunts, otherwise the ratio of transformation of the transformers and the resistance of the shunts must have been previously determined within five years and be on file at the office of the utility.

Connecticut

Rule E-13-b—Meters installed with instrument transformers or shunts may be tested independently of such transformers or shunts provided the utility applies the correction indicated by a certificate from the manufacturer; otherwise the meters and transformers or shunts shall be verified as a measuring unit.

District of Columbia

Rule 2-E—Where meter is installed with instrument transformers and line voltage exceeds 600 volts or the current is greater than 150 amperes, the meter shall be tested self-contained provided transformers have been tested within 5 years preceeding test.

Illinois

Rule 10-d—Watt-hour meters installed with instrument transformers or shunts shall be tested as a unit, unless the ratio of transformation of the transformers and the resistance of the shunts have been previously determined within ten years and are on file at the office of the utility.

Indiana

Rule 14-c—Meters installed with instrument transformers or shunts must be tested jointly with transformers or shunts, otherwise the ratio of transformation of the transformers or the calibration of the shunts must be determined at least every ten years.

Michigan

Rule 35—If watt-hour meter is installed with shunts or instrument transformers it shall be tested jointly with these accessories, provided that if the phase angle and ratio of transformers or the calibration of the shunts is verified previous to the installing of meter, and the meter accordingly adjusted, such test shall not be required.

Instrument transformers used with meters may be used for operating relays only when the total burden does not exceed the rated capacity of the transformers, and provided also that the tests required by the first part of this rule be made with such relays connected to the transformers concerned.

New Hampshire

Rule 3—Meters installed with instrument transformers or shunts must be tested jointly, otherwise the ratio of transformation of transformers or the calibration of the shunts must be determined at least once every five years and records kept of such tests.

New York

Case 278—1921

Section 11—Meters with instrument transformers in circuits exceeding 350 volts shall be tested separately from transformers and the ratio be correctly applied. Meters with transformers or shunts in circuits less than 350 volts may be tested jointly with shunts or transformers.

Section 12—An approved protective short circuiting device shall be permanently installed on current transformer secondary circuits, unless the primary circuit can be open circuited for test.

Section 13—In periodic tests or office tests the transformer or shunt shall have a calibration certificate dated within ten years of the time of test.

Section 14—In complaint tests the Commission will accept the calibration certificates of the transformers or shunts provided they are dated within two years preceding the time the meter is tested.

Section 15—Shunts for direct-current meters exceeding 800 amperes may be permanently installed, provided the calibration certificate is on file dated within the periods specified in Sections 13 and 14.

North Dakota

Rule 14-c—Meters installed with instrument transformers or shunts must be tested jointly with transformers or shunts, otherwise the ratio of transformation of the transformers or the calibration of the shunts must be determined at least once every ten years.

Oklahoma

Rule 15-b—Meters installed with instrument transformers or shunts shall be tested jointly with such transformers or shunts, otherwise the ratio of transformation of the transformers and the resistance of the shunts must have been previously determined within ten years.

Pennsylvania

Rule XXI—When watt-hour meter is connected to line through shunts, multipliers or instrument transformers, the test may be made on the meter as a self-contained unit and the ratio of the accessories may be used to determine the error of the meter, provided the certificates of the accessories bear a date within five years of the test and are satisfactory to the Commission.

Washington

Rule E-16-b—Meters with instrument transformers in circuits exceeding 350 volts shall be tested independently and corrections shown on ratio certificates applied. When circuits are less than 350 volts the certificates need not be supplied if meters are tested jointly with the transformers or shunts.

In periodic tests the ratio certificates should be dated within less than ten years of the test date.

In complaint tests the calibration certificates shall be dated within two years of test date.

Wisconsin

Rule 16—Meters installed with shunts or instrument transformers must be tested jointly with the transformers or shunts otherwise the ratio of transformation of the transformers or the calibration of the shunts must be determined at least once every five years.

Meter Testing Methods and Testing Loads

California

Rule 15—All meters shall be tested before installation.

Colorado

Rule 34-a—Meters shall be tested according to rules and regulations. Light load shall be from 5 to 10 per cent rated capacity of meter, and heavy load shall be from 60 to 100 per cent rated capacity of meter.

Connecticut

Rule E-13—All meters shall be tested in place of permanent location on customers' premises with approved testing apparatus.

Rule E-14—Light load shall be not over 10 per cent of rated capacity of meter and heavy load shall be not less than 60 per cent of rated capacity of meter.

District of Columbia

Rule 2-B—Meters shall be tested in place under operating conditions.

Rule 2-C—Light load shall be 10 per cent of rated capacity of meter and full load between 60 to 100 per cent of rated capacity of meter.

Normal load for request referee and office tests:

Residences and apartments	25 per cent
Elevators	40 per cent
Factories (individual drives), churches and offices	45 per cent
Factories (line shafting), theatres, clubs and stores	60 per cent
Restaurants, pumps and compressors	70 per cent
Signs, show windows and blowers	100 per cent

Illinois

Rule 9-a—Light load shall be between 5 and 10 per cent of rated capacity of meter on induction meters and approximately 10 per cent on commutators and mercury types. Heavy load to be at least 75 per cent of rated capacity of meter. Two observations at least 30 seconds long shall be recorded at each load. The observations must agree within 1 per cent at light load and one-half per cent at heavy load. The error on the two loads shall be averaged and called the average error.

Indiana

Rule 14-a—Meters shall be tested in place of permanent location. Light load shall be not over 10 per cent of rated capacity of meter. Heavy load shall be at least 75 per cent of rated capacity of meter.

Maryland

Rule 6-c—Meters shall be tested in permanent position after installation.

Rule 4-b—Light load shall be between 5 and 10 per cent of rated capacity of meter for induction types and 15 per cent of rated capacity of meter for commutating types. Heavy load shall be 100 per cent rated capacity of meter.

Rule 5-c—Normal load:

Residences and apartments	25 per cent
Elevators	40 per cent
Factories (individual drives), churches and offices	45 per cent
Factories (line shafting), theatres, clubs and stores	60 per cent
Restaurants, pumps and compressors	70 per cent
Signs, show windows and blowers	100 per cent

Michigan

Rule 33—Meters shall be tested in place of permanent location.

Rule 25—Light load shall be between 5 and 10 per cent of rated full load capacity of watt-hour meters and 20 per cent of full load capacity of demand meters. Heavy load shall be approximately 75 per cent of the full load capacity of the meter. The full connected load may be used for full load if this is less than 75 per cent of the rated full load.

Missouri

Rule 31—Light load shall be approximately 5 per cent for induction type meters and 10 per cent for commutator types of meters. Full load shall be 100 per cent rated capacity of meters.

Rule 31—Normal load:

Residences and apartments	25 per cent
Elevators	40 per cent
Factories (individual drives), churches and offices	45 per cent
Factories (line shafting), theatres, clubs and stores	60 per cent
Restaurants, pumps and compressors	60 per cent
Signs, show windows and blowers	100 per cent

Montana

Rule 23—Meters shall be tested in permanent position in place of service.

Rule 22-b—Light load shall be less than 10 per cent of rated capacity of meter. Heavy load shall be at least 75 per cent of rated capacity of meter.

New Hampshire

Rule 1—Meters shall be tested at light, normal and heavy loads. Normal load shall be:

Residences and apartments	25 per cent
Elevators	40 per cent
Factories (individual drives), churches and offices	45 per cent
Factories (line shafting), theatres, clubs and stores	60 per cent
Restaurants, pumps and compressors	70 per cent
Signs, show windows and blowers	100 per cent

New Jersey

Rule XX—Light load shall be between 5 and 10 per cent rated capacity of meter for induction types and between 10 and 15 per cent for commutator types. Full load shall be more than 60 per cent rated capacity of meter. Normal load shall be the following percentages of the 'total connected load:

Residences and apartments	25 per cent
Elevators	40 per cent
Factories (individual drives), churches and offices	45 per cent
Factories (line shafting), theatres, clubs and stores	60 per cent
Restaurants, pumps and compressors	70 per cent
Signs, show windows and blowers	100 per cent

New York

Case No. 278—1921

Section 10—Watt-hour meters shall be tested in the place of permanent location on the consumers' premises and under local conditions of operation.

Section 16—Watt-hour meters on periodic tests shall be tested at light load, normal load and full load. Light load shall be at 10 per cent of rated capacity of meters. Normal load shall be between 50 and 60 per cent of rated capacity of meters. Full load shall be between 85 and 100 per cent of rated capacity of meters.

Section 17—The classification and percentage of installation to be used to obtain normal load on complaint or office tests are given below:

Residences and apartments	25 per cent
Elevators	40 per cent
Factories (individual drives), churches and offices	45 per cent
Factories (line shafting), theatres, clubs and stores	60 per cent
Restaurants, pumps and compressors	70 per cent
Signs, show windows and blowers	100 per cent

Section 18—When an installation consists of more than one of the above classes of loads, normal load shall be obtained by multiplying the watt load of each class by the percentage specified and adding the results.

Section 19—The normal load determination shall include every power, lighting and heating device found so connected that it may be operated by installing fuses, closing a switch or operating a controlling device, or by any combination of these three methods.

North Dakota

Rule 14-a—Watt-hour meters shall be tested in place of permanent position on consumers' premises at light load and heavy load.

Rule 12—Light load shall be 10 per cent of rated capacity of meter. Heavy load shall be at least 75 per cent of rated capacity of meter.

Oklahoma

Rule 15-a—Watt-hour meters shall be tested in place of permanent position under actual conditions at light, normal and heavy loads.

Rule 13-c—Light load shall be between 5 and 10 per cent of rated capacity of meter. Heavy load shall be between 60 and 100 per cent of rated capacity of meter. Normal load shall be:

Residences and apartments	25 per cent
Elevators	40 per cent
Factories (individual drives), churches and offices	45 per cent
Factories (line shafting), theatres, clubs and stores	60 per cent
Restaurants, pumps and compressors	70 per cent
Signs, show windows and blowers	100 per cent

Oregon

Rule 22-a—Meters shall be tested in permanent location on customers' premises. At least two test runs of 30 seconds each which agree within 1 per cent should be made on each load. Meters shall be adjusted to within 1 per cent at three-quarters and one-tenth of rated load.

Pennsylvania

Rule XX—Watt-hour meters shall be tested in place of permanent installation under local conditions with approved equipment.

Rule XII—Light load shall be within 10 per cent of rated capacity of meter for induction types and 10 to 15 per cent rated capacity of meter for commutator and mercury type meters. Heavy load shall be between 75 and 100 per cent rated capacity of meter.

South Carolina

Rule 16—Watt-hour meters shall be tested in place of permanent location under local conditions.

Rule 14—Light load shall be 10 per cent of rated capacity of meter. Heavy load shall be at least 75 per cent of rated capacity of meter.

Washington

Rule E-16—Watt-hour meters shall be tested at light and heavy loads. Light load shall be at least 10 per cent of rated capacity of meter and heavy load shall be from 75 to 100 per cent of rated capacity of meter.

West Virginia

Rule 24-d—Watt-hour meters shall be tested at light, heavy and normal loads. Light load shall be approximately 10 per cent of rated capacity of meter. Full load shall be from 85 to 100 per cent of the rated capacity of the meter. Normal load shall be from 50 to 60 per cent of the rated capacity of the meter.

Wisconsin

Rule 16—Each watt-hour meter shall be checked for accuracy at approximately three-quarters and one-tenth of full load.

Rule 17—Each watt-hour meter must be adjusted if it is found to be in error more than 1 per cent, the tests both before and after adjustments being made at approximately three-quarters and one-tenth of the rated capacity of the meter.

Meter Accuracy Limits

California

Rule 15—No meter shall be in error more than 2 per cent under normal operating conditions.

Colorado

Rule 34—Working standards shall be considered correct when their errors are within 1 per cent, otherwise corrections shall be applied.

Rule 35—Watt-hour meter errors shall be less than 2 per cent plus and 3 per cent minus at light load and 2 per cent plus or minus at heavy load. Watt-hour meters shall not creep.

Connecticut

Rule E-15—Average watt-hour meter errors shall not be in excess of 2 per cent.

District of Columbia

Rule 4—Working standards shall be maintained in proper condition for testing watt-hour meters.

Rule 2-G—Service meters shall not creep, and they shall be adjusted so that their errors are within 1 per cent at light and full loads.

Idaho

Meters shall not vary more than 3 per cent in accuracy.

Illinois

Rule 8-d—Corrections shall be applied to working standards when used for testing service watt-hour meters. The working standard must be correct within 1 per cent or must be adjusted if possible.

Rule 10—Service meters shall not make more than one revolution on no load and shall have an average error less than 2 per cent plus or minus. The error at heavy load shall be within 1 per cent plus or minus, and the error at light load shall be within 4 per cent, plus or minus, for direct-current meters and within 3 per cent, plus or minus, for alternating-current meters.

Indiana

Rule 11—Working standards shall be correct within 1 per cent or corrections shall be applied.

Rule 13—Service watt-hour meters shall not creep and shall have an error less than 4 per cent, plus or minus, on light load, and 1 per cent, plus or minus, on heavy load. The average error shall be not over plus or minus 2 per cent.

Maryland

Rule E-2—Working standards shall be maintained in proper condition for testing service watt-hour meters.

Rule 6-b—Service watt-hour meters shall be adjusted within 1 per cent at light and full loads when found in error more than 2 per cent.

Massachusetts

Section 120—A meter shall be deemed correct for the purpose of this section if it appears from examination or test that it does not vary more than 5 per cent from the standard approved by the department.

Michigan

Rule 45-e—Working standards shall be within 1 per cent correct or corrections shall be applied.

Rule 28—Service watt-hour meters shall not creep and shall have an average error within 2 per cent, plus or minus. The error at heavy load shall be within 1 per cent, plus or minus, and the error at light load shall be within 3 per cent, plus or minus.

Missouri

Rule 35—Corrections shall be applied to all working standards when used to check service watt-hour meters.

Rule 29—Watt-hour meters shall be adjusted as accurately as possible on light and full load.

If it becomes necessary to make adjustment for normal load or for inductive load, the meter may be adjusted fast at light or full load, but such adjustment must not exceed 2 per cent.

Rule 31—Meters tested after being in service may be considered as recording within allowable limits if correct within 4 per cent. After such test the accuracy must be adjusted according to Rule 29.

Montana

Rule 27—Working standards shall have an error of less than 1 per cent or corrections shall be applied.

Rule 24—Service meters shall have errors within 4 per cent and shall not creep.

New Hampshire

Rule 9—Working standards shall be maintained correct within one-half of 1 per cent, or corrections shall be applied.

Rule 2—Service watt-hour meters shall have an error less than 4 per cent at light, normal or heavy loads.

New Jersey

Rule XIX—Corrections shall be applied to all working standards when used to check service watt-hour meters.

Rule XX—Service watt-hour meters shall have an error less than 4 per cent, plus or minus, and shall not creep.

New York

Case No. 278—1921

Section 27—Corrections shall be applied to working standards when used to check service meters.

Section 22—Service watt-hour meters shall be adjusted to register with an error not more than 1 per cent at 10 per cent and at 100 per cent capacity, and shall be maintained in this condition as nearly as possible.

North Dakota

Rule 11-c—Working standards shall not have an error greater than 1 per cent.

Rule 13-e—A service watt-hour meter having an average error of not more than plus or minus 4 per cent may be considered correct as far as adjustments of charges are concerned.

Oklahoma

Rule 12—Working standards shall be within 1 per cent correct or corrections shall be applied.

Rule 13-b—Service watt-hour meters shall have an average error less than 2 per cent and shall not creep.

Oregon

Rule 21-a—Meters shall be adjusted to be correct within 1 per cent at approximately three-quarters and one-tenth of rated load.

Pennsylvania

Rule XV—Corrections shall be applied to working standards at all times.

Rule XI—Service meters shall not have an error greater than 4 per cent and shall not creep.

South Carolina

Rule 13—Working standards shall be maintained in proper conditions to make accurate tests of service meters.

Rule 15-d—Service meters shall not have an error greater than 3 per cent, plus or minus, and shall not creep.

Washington

Rule E-11—Working standards shall not be in error more than 1 per cent, otherwise corrections shall be applied.

Rule E-12—Service meters shall not be in error more than 4 per cent between 10 per cent and full load, and shall not creep.

West Virginia

Rule 23—Working standards shall be maintained in proper condition for accurately testing service watt-hour meters.

Rule 24-a—Service meters shall have an error less than 1 per cent at light and normal loads, and shall not creep.

Wisconsin

Rule 19—Working standards shall be maintained within one-half of 1 per cent correct, or corrections shall be applied to all tests.

Rule 15—Service meters shall not be in error more than 4 per cent between 10 per cent and full connected load, and shall not creep.

Meter Locations

California

Rule 13-b—All meters shall be installed in some convenient place accessible for inspection, reading and testing.

Colorado

Rule 33—Meters shall be located in the cellar or first floor as near as possible to service entrance in a clean, dry place, not subject to vibration or great variations in temperature. Meters must not be set in coal or wood bins or on the partitions of same, or where meter readers or meter testers would annoy consumer.

When several meters are on one meter board, the distance between centers should be at least 15 in., and meters shall be not less than 4 ft. or more than 7 ft. above the floor. Meters may be placed out of doors if properly protected from the elements.

Connecticut

Rule E-11—Meters should be located in the cellar or first floor as near as possible to the service entrance in a clean, dry, safe place, not subject to great variations in temperature and free from vibration. Meters shall be accessible for reading and testing; they shall not be placed in coal or wood bins or on the partitions forming the same or on any unstable partitions or supports, nor in attics, sitting rooms, bedrooms, bathrooms, restaurant kitchens, over doors, over windows or in any location where the visits of the meter reader or tester will cause annoyance to the consumer.

District of Columbia

Rule 1—Meters shall be located as near as possible where the service enters and shall be accessible with a minimum of annoyance to the tenants and with sufficient space for testing apparatus. They shall be installed on a stable support in a clean, dry place, not subject to great variations in temperature nor great vibration. When more than one meter is on the same meter board, the distance between centers shall be not less than 15 in. for commutator type meters, or 12 in. for mercury type meters, or 10 in. for induction type meters.

Illinois

Rule 7—Meters shall be located in basement or on first floor as near as possible to service entrance. They must not be installed where the accuracy would be affected by exposure to the elements or in coal or wood bins or any partitions forming the same, or in attics, bedrooms, toilet rooms, over doors, over windows, or any place where the meter reader or tester would cause annoyance to the consumer.

Indiana

Rule 10—Meters shall be located in the cellar or first floor as near as possible to service entrance in a clean, dry place, not subject to vibration or great variations in temperature. They must not be set in coal or wood bins or partitions of same, or where meter readers and testers would annoy the consumer.

When several meters are on one board, the distance between centers shall be not less than 15 in., and no meter shall be less than 4 ft. or more than 7 ft. above the floor.

Meters may be installed out of doors if properly protected from the elements.

Michigan

Rule 19—Meters shall be installed in cellar or first floor as near as possible to service entrance in a clean, dry place, not subject to vibration or great variations in temperature; if installed out of doors they must be protected from the elements.

Rule 20—Meters shall not be less than 4 ft. nor more than 7 ft. above the floor and shall be easily accessible.

Rule 21—When more than one meter is installed on one meter board, there shall be a clearance between meters of 4 in. for horizontal dimensions and 6 in. for vertical dimensions. For direct current meters, the distance shall be such as to prevent errors due to current in adjacent meters.

Rule 22—Meters should not be placed in basements where the only entrance is through a trap door, or on lattice or metal lath partitions. Meters should not be placed in coal or wood bins or on the partitions of such bins, or in sheds, attics, bedrooms, bathrooms, toilet rooms, restaurant kitchens, stairways or ventilating shafts, or in any place where the visits of the meter reader will cause inconvenience either to the consumer or the meter reader.

Rule 23—Meters should not be placed over windows, doors, stoves, sinks, tubs or in any place subject to flyings or excessive moisture or other fumes. Where it is necessary to install them in places subject to flyings, moisture or fumes, they should be protected by a suitable inclosure. Meters should not be placed in the neighborhood of gas, steam, water or other piping, or near belts and moving machinery. They should be placed at least 10 ft. and, if possible, 15 ft. from any electrical machinery, and at least 18 in. from any conductors carrying a current exceeding 100 amperes, excepting such conductors as carry current to the meters concerned.

Rule 24—In cases where it is necessary to recess a meter in the wall, a cabinet shall be provided, the walls and doors of which must be made of some fireproof material.

Montana

Rule 21—Meters shall be installed in cellar or first floor in a clean, dry place free from vibration and great changes in temperature. They must not be installed in coal or wood bins or on the flimsy partitions forming the same. If installed in stores, they shall be located where merchandise will not be piled in front of them. Meters shall be accessible at all reasonable hours without annoyance to consumer.

When several meters are installed, they shall be grouped and be not less than 15 in. between centers, and they shall be joined to well marked, continuous conduit.

New Jersey

Rule XVII—Meters shall be located in the cellar or first floor as near as possible to service entrance. No meter shall be less than 3 ft. nor more than 7 ft. above the floor, and must not be installed in or on coal or wood bins or flimsy partitions or supports, nor in attics, bedrooms, bathrooms, etc., where meter readers or testers will inconvenience or annoy the consumer.

All meters shall be installed strictly according to the National Electrical Code, current edition.

New York

Case No. 2115-1917

1. Meters shall be installed in a clean, dry, safe place not subject to vibration or great variations in temperature.

2. Where it is necessary to install meters in locations exposed to weather conditions, they shall be protected by suitable boxes or cabinets.

3. Meters should be easily accessible for reading, testing and making necessary adjustments and repairs.

North Dakota

Rule 10—Meters shall be installed in cellar or first floor as near as possible to service entrance in a clean, dry place, free from vibration and great variations in temperature, where the visits by meter reader or tester will not annoy the consumer.

Where several meters are grouped they shall be not less than 15 in. between centers and not less than 4 ft. nor more than 7 ft. above the floor.

Oklahoma

Rule 11—Meters shall be installed in cellars or first floors at the service entrance in a clean, dry, safe place, free from vibration and great temperature variations, on a support furnished by the consumer and where the readers or testers will not annoy consumer. Meters may be installed on porches or out of doors if properly protected from the weather.

Where there are several meters they shall be not less than 12 in. between centers, and not less than 4 ft. nor more than 7 ft. above the floor.

South Carolina

Rule 12—Meters shall not be installed where it is extremely hot, cold or damp or inaccessible, or on unstable supports or in coal or wood bins.

Where meters are grouped on one meter board, they should be not less than 15 in. between centers, and each wiring loop shall be marked plainly.

The customer shall provide suitable location for the meters where they will be accessible without annoyance at any reasonable hour.

Washington

Rule E-10—All new meters shall be installed as near as possible to the service entrance in clean, dry, safe places not subject to great temperature variations or vibrations, or where reading or testing of the meters shall annoy the consumer.

West Virginia

Rule 26—Meters shall be installed as near as possible to the service entrance in a clean, dry place, easily accessible and not on flimsy partitions. A board at least ¾ in. thick with one or more coats of paint and mounted not less than 5 ft. and not more than 7 ft. from the floor shall be provided to hold the meter. There shall be a 6-in. clearance all around the meter board and 30 in. in front of it. All the meters for one building shall be grouped at one place.

Installation Tests

California

Rule 15—All meters shall be tested before installation.

Colorado

Rule 36—All meters shall be tested before installation or within 60 days thereafter.

Connecticut

Rule 4—Meters shall be tested before installation or within 60 days thereafter.

Rule E-16—Meters shall be checked within 60 days after installation for correct connections, proper mechanical conditions and suitability of location.

District of Columbia

Rule 5—Tests shall be made on all direct-current meters after installation, before large registration appears on meter. An installation test, or an installation inspection, shall be made on all induction type meters.

Illinois

Rule 13-a—Each meter shall be checked for correct connections, proper mechanical condition and suitability of location in its permanent location within 60 days of installation.

Indiana

Rule 14-a—Each meter shall be checked for correct connections, proper mechanical condition and suitability of location in its permanent location within 60 days of installation.

Maryland

Rule 6—Induction type meters shall be tested before installation or within 30 days thereafter. All other type meters shall be tested within 60 days after installation.

Michigan

Rule 33—All watt-hour meters and demand meters shall be checked in position at time of installation or within 30 days thereafter.

Rule 34—All watt-hour meters and demand meters operating on a highly inductive circuit shall be tested in position at time of installation, or within 30 days thereafter, on the connected load, approximating light and heavy loads, and shall be readjusted if necessary.

Missouri

Rule 29—Each meter shall be tested before installation or within 30 days thereafter, but preferably after it has been set, when it can also be checked for location, mechanical condition and correct connection. Commutator meters should be allowed when feasible to remain in actual service at least 5 days before testing.

Montana

Rule 22-c—Meters shall be tested just before installation or within 60 days thereafter.

New Hampshire

Rule 3—Meters shall be tested within 60 days of installation.

New Jersey

Rule XXIII—Meters shall be tested within 30 days after installation or just before installation.

New York

Case No. 278—1921

Section 7—Meters shall be tested and adjusted before installation or within 60 days thereafter. Direct-current meters shall be tested and adjusted within 60 days after installation.

North Dakota

Rule 14-a—Meters shall be tested at time of installation or within 60 days thereafter.

Oklahoma

Rule 16-a—Induction type meters shall be tested before installation or within 60 days thereafter. Direct-current meters shall be tested in place of permanent location within 60 days after installation.

Oregon

Rule 21-a—Meters shall be tested at time of installation or within 30 days.

Pennsylvania

Rule XIV—Meters shall be tested within 90 days before installation and 60 days after installation.

South Carolina

Rule 15-b—Meters shall be tested before installation.

Washington

Rule E-9-c—Meters shall be tested within 60 days after installation or immediately before installation.

West Virginia

Rule 24-a—Meters shall be tested before installation.

Wisconsin

Rule 16—Meters shall be tested within 30 days after installation.

Periodic Tests

Colorado

Rule 37—Direct-current meters up to and including 15 amperes shall be tested every 24 months.

Direct-current meters exceeding 15 amperes up to and including 500 amperes shall be tested every 18 months.

Direct-current meters exceeding 500 amperes shall be tested every 12 months.

Alternating-current, single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current, single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase meters in circuits up to 50 kilovolt-amperes shall be tested every 24 months.

Polyphase meters in circuits exceeding 50 kilovolt-amperes shall be tested every 12 months.

Connecticut

Rule E-17—Direct-current meters up to and including 50 amperes shall be tested every 18 months.

Direct-current meters exceeding 50 amperes shall be tested every 12 months.

Alternating-current, single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current, single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase self-contained meters up to and including 50 kilovolt-amperes rating shall be tested every 18 months.

Polyphase self-contained meters exceeding 50 kilovolt-amperes rating shall be tested every 12 months.

Polyphase meters with transformers connected in circuits up to and including 50 kilovolt-amperes shall be tested every 24 months.

Polyphase meters with transformers connected in circuits exceeding 50 kilovolt-amperes shall be tested every 18 months.

District of Columbia

Rule 7—Direct-current meters up to and including 25 amperes shall be tested every 30 months.

Direct-current meters exceeding 50 amperes and up to and including 500 amperes shall be tested every 18 months.

Direct-current meters exceeding 500 amperes shall be tested every 6 months.

Alternating-current, single-phase meters up to and including 25 amperes shall be tested every 48 months.

Alternating-current, single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase meters up to and including 50 kilovolt-amperes shall be tested every 24 months.

Polyphase meters exceeding 50 kilovolt-amperes shall be tested every 12 months.

Illinois

Rule 14—Direct-current meters up to and including 50 amperes shall be tested every 18 months.

Direct-current meters exceeding 50 amperes shall be tested every 12 months.

Alternating-current, single-phase meters up to and including 25 amperes shall be tested every 48 months if they meet the requirements of the Code for Electricity Meters, Third Edition. Otherwise they must be tested every 30 months.

Alternating-current, single-phase meters, exceeding 25 amperes shall be tested every 24 months.

Polyphase, self-contained meters up to and including 50 kilovolt-amperes shall be tested every 24 months.

Polyphase self-contained meters exceeding 50 kilovolt-amperes shall be tested every 12 months.

Polyphase meters with transformers connected in circuits up to and including 50 kilovolt-amperes shall be tested every 24 months.

Polyphase meters with transformers connected in circuits exceeding 50 kilovolt-amperes shall be tested every 18 months.

At the time the watt-hour meter is tested any demand meter associated with it shall be inspected or tested. Each demand meter shall be tested at least as often as the meter with which it is associated and as nearly as practicable at the same time.

Indiana

Rule 15—Direct-current meters up to and including 50 amperes shall be tested every 18 months.

Direct-current meters exceeding 50 amperes shall be tested every 12 months.

Alternating-current, single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase self-contained meters up to and including 50 kw. shall be tested every 18 months.

Polyphase self-contained meters exceeding 50 kw. shall be tested every 12 months.

Polyphase meters with transformers connected in cricuits up to and includng 50 kw. shall be tested every 24 months.

Polyphase meters with transformers connected in circuits exceeding 50 kw. shall be tested every 18 months.

Maryland

Rule 6—All induction type meters shall be tested once every 36 months. All other types of meters shall be tested once every 18 months.

Michigan

Rule 36—Direct-current type meters not over 50 amperes shall be tested every 24 months.

Direct-current type meters exceeding 50 amperes and up to and including 500 amperes shall be tested every 12 months.

Direct-current type meters exceeding 500 amperes shall be tested every 6 months.

Alternating-current, single-phase meters up to and including 25 amperes shall be tested every 48 months.

Alternating-current, single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase meters up to and including 50 kilovolt-amperes shall be tested every 24 months.

Polyphase meters exceeding 50 kilovolt-amperes shall be tested every 12 months.

Missouri

Rule 32—Induction type meters not exceeding 50 amperes shall be tested every 24 months.

Induction type meters exceeding 50 amperes shall be tested every 12 months.

Direct-current meters not exceeding 50 amperes and 250 volts shall be tested every 12 months.

All other types of meters shall be tested every 6 months.

Montana

Rule 23—Direct-current meters up to and including 25 amperes shall be tested every 24 months.

Direct-current meters exceeding 25 amperes shall be tested every 18 months.

Alternating-current, single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current, single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase self-contained meters up to and including 50 kw. shall be tested every 18 months.

Polyphase self-contained meters exceeding 50 kw. shall be tested every 12 months.

Polyphase meters connected with instrument transformers shall be tested every 24 months.

New Hampshire

Rule 4—Induction type single-phase meters up to and including 50 amperes shall be tested every 24 months.

Induction type single-phase meters exceeding 50 amperes shall be tested every 12 months.

Polyphase meters up to and including 25 amperes shall be tested every 24 months.

Polyphase meters exceeding 25 amperes shall be tested every 12 months.

Direct-current meters of all ratings shall be tested every 12 months.

New Jersey

Rule XVIII—Direct-current meters up to and including 25 amperes shall be tested every 13 months. (This figure is a typographical error in the original Public Utility Commission Publication. The correct figure in effect in New Jersey is 18 months.)

Direct-current meters exceeding 25 amperes up to and including 500 amperes shall be tested every 12 months.

Direct-current meters exceeding 500 amperes shall be tested every 6 months.

Alternating-current single-phase meters up to and including 50 amperes shall be tested every 48 months.

Alternating-current single-phase meters exceeding 50 amperes shall be tested every 24 months.

Polyphase meters up to and including 150 amperes shall be tested every 24 months.

Polyphase meters exceeding 150 amperes shall be tested every 12 months.

New York

Case No. 278—1921

Section 8—All direct-current meters installed on customer's premises shall be periodically tested as follows:

(a) Meters up to and including 25 amperes shall be tested every 30 months.

(b) Meters exceeding 25 amperes up to and including 200 amperes shall be tested every 18 months.

(c) Meters exceeding 200 amperes up to and including 400 amperes shall be tested every twelve months.
(d) Meters exceeding 400 amperes shall be tested every six months.

Section 9—All alternating-current meters installed on customer's premises shall be periodically tested as follows:

(a) Single-phase meters up to and including 25 amperes shall be tested every 60 months.
(b) Single-phase meters exceeding 25 amperes shall be tested every 24 months.
(c) Polyphase meters up to and including 150 amperes shall be tested every 24 months.
(d) Polyphase meters exceeding 150 amperes shall be tested every 12 months.
(e) Single-phase or polyphase meters up to and including 100 kw. on circuits having a voltage of 2000 volts and over shall be tested every 12 months.
(f) Single-phase or polyphase meters exceeding 100 kw. on circuits having a voltage of 2000 volts and over shall be tested every six months.

North Dakota

Rule 15—Direct-current meters up to and including 50 amperes shall be tested every 18 months.

Direct-current meters exceeding 50 amperes shall be tested every 12 months.

Alternating-current single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase self-contained meters up to and including 50 kw. shall be tested every 18 months.

Polyphase self-contained meters exceeding 50 kw. shall be tested every 12 months.

Polyphase meters with transformers up to and including 50 kw. shall be tested every 24 months.

Polyphase meters with transformers exceeding 50 kw. shall be tested every 18 months.

Oklahoma

Rule 17—Direct-current meters up to and including 50 amperes shall be tested every 24 months.

Direct-current meters exceeding 50 amperes up to and including 500 amperes shall be tested every 18 months.

Direct-current meters exceeding 500 amperes shall be tested every 6 months.

Induction type meters, single-phase, up to and including 25 amperes shall be tested every 48 months.

Induction type meters, single-phase, exceeding 25 amperes shall be tested every 24 months.

Polyphase meters up to and including 50 kilovolt-amperes shall be tested every 24 months.

Polyphase meters exceeding 50 kilovolt-amperes shall be tested every 12 months.

Polyphase meters with transformers up to and including 50 kilovolt-amperes shall be tested every 24 months.

Polyphase meters with transformers exceeding 50 kilovolt-amperes shall be tested every 18 months.

Oregon

Rule 22—Single-phase meters up to and including 50 amperes shall be tested every 36 months.

Single-phase meters over 50 amperes shall be tested every 12 months.

Polyphase meters not exceeding 550 volts and 50 amperes shall be tested every 12 months.

Direct-current meters not exceeding 550 volts and 50 amperes shall be tested every 12 months.

All other meters shall be tested every 6 months.

Pennsylvania

Rule XVI—Direct-current meters up to and including 50-amperes shall be tested every 18 months.

Direct-current meters exceeding 50 amperes shall be tested every 12 months.

Alternating-current single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase self-contained meters up to and including 50 kw. shall be tested every 18 months.

Polyphase self-contained meters exceeding 50 kw. shall be tested every 12 months.

Polyphase meters with transformers up to and including 50 kw. shall be tested every 24 months.

Polyphase meters with transformers exceeding 50 kw. shall be tested every 18 months.

South Carolina

Rule 16—Direct-current meters up to and including 50 amperes shall be tested every 18 months.

Direct-current meters exceeding 50 amperes shall be tested every 12 months.

Alternating-current single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase self-contained meters up to and including 50 kw. shall be tested every 18 months.

Polyphase self-contained meters exceeding 50 kw. shall be tested every 12 months.

Polyphase meters with transformers up to and including 50 kw. shall be tested every 24 months.

Polyphase meters with transformers exceeding 50 kw. shall be tested every 18 months.

Washington

Rule E-14—Direct-current meters up to and including 25 amperes shall be tested every 24 months.

Direct-current meters between 25 amperes and 200 amperes shall be tested every 18 months.

Direct-current meters exceeding 200 amperes up to and including 400 amperes shall be tested every 12 months.

Direct-current meters exceeding 400 amperes shall be tested every 6 months.

Alternating-current single-phase meters up to and including 25 amperes shall be tested every 60 months.

Alternating-current single-phase meters exceeding 25 amperes up to and including 75 amperes shall be tested every 36 months.

Alternating-current single-phase meters exceeding 75 amperes shall be tested every 24 months.

Polyphase meters up to and including 50 kw. shall be tested every 36 months.

Polyphase meters exceeding 50 kw. up to and including 150 kw. shall be tested every 24 months.

Polyphase meters exceeding 150 kw. shall be tested every 12 months.

Alternating-current meters in circuits exceeding 2000 volts shall be tested every 12 months.

West Virginia

Rule 27—Direct-current meters up to and including 25 amperes shall be tested every 18 months.

Direct-current meters exceeding 25 amperes up to and including 500 amperes shall be tested every 12 months.

Direct-current meters exceeding 500 amperes shall be tested every 6 months.

Alternating-current single-phase meters up to and including 25 amperes shall be tested every 36 months.

Alternating-current single-phase meters exceeding 25 amperes shall be tested every 24 months.

Polyphase meters exceeding 50 kw. shall be tested every 12 months.

Wisconsin

Rule 17—Alternating-current single-phase meters up to and including 50 amperes shall be tested every 48 months

Alternating-current single-phase meters exceeding 50 amperes shall be tested every 12 months.

Polyphase meters in circuits under 250 volts and 50 amperes rating shall be tested every 12 months.

Direct-current meters in circuits under 250 volts and 50 amperes rating shall be tested every 12 months.

All other types of meters shall be tested every 6 months.

Request and Referee Tests

California

Rule 15—Each utility will make a test on service meters upon consumers' requests.

Colorado

Rule 38—Each utility will test service meters upon request of consumer, if more than than 12 months have elapsed since the last regular test.

Rule 39—Public Service Commission will test consumer's meter upon written application to the Commission.

Connecticut

Rule 5—Utilities will test service meters upon written request of the consumer if more than one year has elapsed since last test.

The Public Service Commission will test service meters upon formal petition to the Commission.

District of Columbia

Rule 6—Each utility will test consumers' meters upon request if not more often than every 6 months.

Rule 10—Public Service Commission will test service meters upon formal application.

Idaho

Request tests shall be made when not requested oftener than twice a year.

Illinois

Rule 15—Each utility will test consumer's meter upon request if not within 6 months of last previous test.

Rule 16—Public Service Commission will test service meters upon written application.

Indiana

Rule 16—Each utility will test consumer's meter upon request if not more often than once every 12 months.

Rule 17—The Public Service Commission will test service meters upon formal application to the Commission.

Maryland

Rule 5—Each utility will make test of consumer's meter upon request, if meter has not been checked within one year.

The Public Service Commission will test service meters upon written formal application to the Commission.

Massachusetts

Section 120—Public Utility Commission will test service meters upon application.

Michigan

Rule 50—Utility will test consumer's meter upon request if not more often than once in six months.

Rule 51—Public Service Commission will test service meters upon formal application to the Commission.

Missouri

Rule 33—Utility shall make test of consumer's meter upon request if it has not been tested within 6 months. The consumer shall be notified of the time of test so that he may witness the test if he desires.

Rule 34—Upon written request to the School of Engineering of Missouri State University a referee test will be made on any service meter.

Montana

Rule 25—Utility will make test of consumer's meter upon request if not more often than once in 12 months.

The Public Service Commission will test any service meter upon written application to the Commission.

New Hampshire

Rule 5—Utility will make test of consumer's meter upon request if not more often than once in 6 months.

Rule 6—The Public Service Commission will make a test of any service meter upon formal application to the Commission.

New Jersey

Rule XXV—Utility will test consumer's meter upon request if not more often than 6 months.

Rule XXVI—The Public Service Commission will test any service meter upon formal application to the Commission.

New York

Case No. 278—1921

Section 1—A complaint test is a test of a meter made by an electrical corporation on the premises where the meter is installed, as a result of a complaint of the consumer.

North Dakota

Rule 16—Utility will test consumer's meter upon request if not more often than once in 12 months.

Rule 17—The Public Service Commission will test any service meter upon formal application to the Commission.

Oklahoma

Rule 18—Utility will test consumer's meter upon request if not more often than once each year.

Rule 19—The Public Service Commission will test any service meter upon formal application to the Commission.

Oregon

Rule 5-a—Utility shall test consumer's meter upon request if the meter has not been tested within a year, either by the utility or by the Commission.

Rule 5-b—Commission will make test for a fee.

Pennsylvania

Rule XVIII—Utility will test consumer's meter upon request of consumer.

South Carolina

Rule 17—Utility will test consumer's meter upon request if not more often than once in 6 months.

West Virginia

Rule 29—Utility will make test of consumer's meter upon request if not more often than once in 12 months.

Rule 28—The Public Service Commission will test any service meter upon formal application.

Wisconsin

Rule 20—Utility will test consumer's meter upon request if not more frequent than every 6 months.

Rule 21—The Public Service Commission will test any service meter upon written application to the Commission.

Original Test Records

Colorado

Rule 6-b—The original meter test record shall be kept with identification data reasons for the test, reading of the meter if removed and all necessary data to permit check on the methods and calculations of the test.

Connecticut

Rule 3-c—Original records of service meter tests shall be preserved and shall show the following:

1st—Identification of meter
2nd—Reading of meter
3rd—Computed accuracy "as found" and "as left"
4th—Sufficient data to permit the checking of methods and computations.

District of Columbia

Rule 8—A complete record shall be kept of all tests of meters made on consumers' premises.

Illinois

Rule 3-a—Records shall be kept of all tests for accuracy of meters and shall include the following:

1st—Identification data
2nd—Reason for test
3rd—Time and reading of meter
4th—Person making the test
5th—Statement about creepage
6th—accuracy "as found" and "as left" in tenths of 1 per cent and necessary data for checking methods of calculation.

Indiana

Rule 8-a—The original record shall be kept to identify each meter, reason for the test, the reading of the meter, the result of test and sufficient data to check method and calculation.

Maryland

Rule F-3—The original test record shall be kept showing the following:

1st—Identification of meter
2nd—Reason for test
3rd—Reading of meter
4th—Result of test
5th—Data for checking methods and calculation.

Massachusetts

Original test records shall be kept six (6) years.

Michigan

Rule 17—Original records of all meter tests shall be kept showing the following:

1st—Identification data
2nd—Reason for test
3rd—Reading of dial before and after test
4th—Accuracy before and after adjustment
5th—Data for checking test.

Missouri

Rule 2—Original test records shall be kept for at least two years and shall include the following:

1st—Identification data
2nd—Date and place of test
3rd—Person making the test
4th—Reason for the test
5th—Method of test
6th—Reading of meter before test
7th—Statement about creepage
8th—Result of test and data to allow check on calculation.

Montana

Rule 28-a—A complete record shall be kept showing the following:

1st—Identification data
2nd—Reason for test
3rd—Reading of meter
4th—Result of test
5th—Necessary data for checking methods employed.

New Hampshire

Rule 10—Original test records shall be kept showing identification, reasons for test, reading of meter, statement on creepage and all data to permit check on methods of calculation.

New Jersey

Rule XXIV—A complete record shall be kept of all tests.

New York

Case No. 278—1921

Section 6—A record of tests of each meter shall be continuous for a period of not less than 5 years, and in any event of sufficient length to cover three consecutive periodic tests.

North Dakota

Rule 8-a—A record shall be kept showing the following:

1st—Identification data
2nd—Reason for test
3rd—Reading of meter
4th—Result of test
5th—Data for checking methods and calculations.

Oklahoma

Rule 20-c—A complete record shall be kept of all tests made on electric meters for at least two periodic test periods.

Oregon

Rule 3—All original meter test records shall be kept accessible to the public and shall include:

1st—Date and hour of test
2nd—Name of tester
3rd—Number and capacity of meter
4th—Identification
5th—Reason for test
6th—Reading of meter
7th—Accuracy and necessary data for checking the calculations.

South Carolina

Rule 4-a—A complete record shall be kept of all tests and inspections made on consumers' premises.

Washington

Rule E-17—A complete record shall be kept of all tests of electric meters.

West Virginia

Rule 25—A complete record shall be kept of all tests with sufficient data for checking the tests and calculations. Such records shall be reported monthly to the Commission.

All electric meters shall be given a company number.

Wisconsin

Rule 18—Original test records shall be kept to identify each meter, reasons for test, reading of meter, statement on creepage and sufficient data to permit the checking of methods and calculations.

Meter Records

Colorado

Rule 6—Meter record shall show the following:

1st—Date of purchase of meter
2nd—Manufacturer's serial number
3rd—Record of use
4st—Tests made on meter
5th—Present location of meter.

Rule 38—A record shall be kept of all request tests.

Connecticut

Rule 3-d—Meter records shall be systematically arranged showing the following:

1st—Approximate date of purchase
2nd—Size or capacity of meter
3rd—Various places of installation
4th—Date of each repair, adjustment or test
5th—Reason for each test
6th—Result of each test.

All records other than those as above specified shall be preserved at least three years. Those specified above shall be kept until meter is destroyed or permanently removed from service.

District of Columbia

Rule 8—Meter records shall contain the following:
1st—Company number
2nd—Manufacturers' name and serial number
3rd—Type, volts, amperes and wire
4th—Average readings at light load, normal load and full load
5th—Date meter was installed and removed.

Rule 9—A monthly report of all tests shall be sent to the Commission on or before the 15th of the month.

Illinois

Rule 2—Meter and associated apparatus records shall include the following:
1st—Date of purchase
2nd—Company's number
3rd—Nameplate data
4th—Places of installation with the dates of installation and removal and the reason for the removal
5th—Dates and results of tests, repairs and final disposition.

Rule 3-b—Each utility with more than 250 meters shall make monthly and annual tabulations of the results of all tests on consumers' premises except initial tests and shop tests.

Rule 5-b—A complete record shall be kept of all complaints, including the name and address of consumer, the date, the nature of the complaint and the disposal of same.

Indiana

Rule 8-b—A numerical record shall be kept giving the following:
1st—Date of purchase
2nd—Identification
3rd—All tests on meters.

Rules 8-c—Annual tabulations of test results arranged according to types and intervals shall be made.

Rule 7—A record shall be kept of all complaints in regard to service, giving the name and address of the consumer, the date, the nature of complaint and the remedy.

Rule 9—Reports shall be submitted to the Commission as required.

Massachusetts

Meter records shall be kept six years.

Maryland

Rule F-4—A numerically arranged record shall be kept showing:
1st—Date of purchase of meter
2nd—Record of use and repairs
3rd—Results of tests
4th—Present location of meter.

Rule G—Reports shall be made to the Commission as and when called upon by the Commission.

Rule I—A record shall be kept of all complaints showing:
1st—Name and address of complainant
2nd—Date of complaint
3rd—Character of complaint
4th—Adjustment made.

Michigan

Rule 16—Records of meters owned or used shall be kept numerically arranged and properly classified, showing:
1st—Identification number
2nd—Date of purchase
3rd—Manufacturer
4th—Serial number
5th—Type and rating
6th—All installations and removals of the meter with names of consumers
7th—All tests and their results.

Rule 18—A periodic summary of all tests shall be made showing meters classified as to manufacturer, type, accuracy limits, intervals between tests and other information which may be conveniently summarized.

Rule 50—A record shall be kept in the utility office of all request tests.

Missouri

Rule 2—An alphabetical record shall be kept of all consumers with addresses and identification numbers of meters in use by consumers.

A numerical record shall be kept in accordance with the utility's numbers, indicating a proper description, date of purchase, record of use, repairs, adjustments and tests and present location of meter.

Montana

Rule 28-c—A numerically arranged record shall be kept showing:
1st—Date of purchase of meter
2nd—Identification number
3rd—Tests and results.

Rule 28-d—Annual tabulations or results of all tests shall be kept according to types of meters and intervals of tests.

Rule 29—Records shall be kept of all complaint tests and their disposal.

New Hampshire

Rule 10—A meter record shall be kept arranged numerically, showing:
1st—Purchase date
2nd—Identification
3rd—Places of installation and removal
4th—Dates and results of all tests.

New Jersey

Rule XXIV—A complete record shall be kept of all tests.

A periodic report shall be made to the Board giving a summary of the periodic, complaint and removal tests each month when more than 500 meters are involved, and quarterly when less than 500 meters are involved.

New York

Case No. 278—1921

Section 5—A meter record shall be kept showing:
1st—Owning company's number
2nd—Manufacturer's name and number
3rd—Type, rated volts, amperes and wire
4th—Date of each installation, removal and test.
5th—Average of the readings at full load, at light load and at normal load as found at each and every test, hereinafter prescribed.

North Dakota

Rule 8-b—A numerically arranged record shall be kept showing:

1st—Date of purchase of meter
2nd—Identification number
3rd—Tests and results.

Rule 8-c—Annual tabulation of test results shall be arranged according to types of meters and intervals of tests.

Rule 7—A record shall be kept of all complaint tests and disposal of same.

Oklahoma

Rule 20-a—A meter record shall be kept showing:
1st—Names and addresses of consumers with company serial numbers of the meters used by them
2nd—Date of purchase of meters, installation and removal.

Rule 20-b—A record shall be kept showing:
1st—Utility's number of meter
2nd—Manufacturer's name and serial number
3rd—Type and capacity

4th—Constants
5th—Date and kind of tests
6th—Per cent accuracy at heavy and light loads "as found" and "as left."

Rule 20-d—Such reports as are required shall be submitted to the Commission.

Oregon

Rule 3-c—A systematic record must be kept showing the following:
1st—Date of purchase
2nd Capacity and identification
3rd—Places of installation and removal
4th—Dates and general results of tests.

Pennsylvania

Rule XIII—Records shall be kept showing:
1st—Name of manufacturer
2nd—Type and rating
3rd—Date of purchase
4th—Date and location of all installations and removals
5th—Dates of all tests
6th—Reasons for tests
7th—Error "as found" and "as left."

Rule VI—A record shall be kept of all complaints from consumers regarding service and shall show the name and address of complainant, date and nature of complaint and the action taken with the date.

South Carolina

Rule 4-b—Records shall be kept showing:
1st—Date, time and place of test
2nd—Name of person making test
3rd—Result of test.

Rule 5—Each utility shall make reports to Commission as ruled.

Washington

Rule E-17—A record shall be kept showing:
1st—Utility's number of meter
2nd—Manufacturer's name and number
3rd—Type, volts, amperes and wire
4th—Date of each installation, removal and test
5th—Average of readings at full load and light load.

A test card shall be filed for each portable standard meter.

A copy of the approved form of calibration card for indicating and rotating reference standards shall be filed with the Commission.

West Virginia

Rule 25-d—A separate card for each meter shall be kept on file showing the date and data of each test with a marker showing the date for the next periodic test.

Wisconsin

Rule 18—All utilities with more than 250 meters in service shall have a numerically arranged record showing:
1st—When the meter was purchased
2nd—Identification of meter
3rd—Places of installation and removal
4th—Dates and results of all tests.

A monthly tabulation and an annual tabulation shall be made of the results of all tests according to types of meters and intervals of tests.

Adjustment of Bills

California

Rule 16—When meters are more than 2 per cent fast a refund shall be made to the consumer for the overcharge for the period meter was incorrect; this period shall not exceed six months.

If meter does not register more than 75 per cent of the actual consumption, the average amount not registered may be estimated and billed the consumer, subject to review of the Commission.

If the meter is more than 2 per cent slow, the utility may render a bill for the extra due, not to exceed a period of three months and subject to review by the Commission.

Colorado

Rule 40—When a meter is faster than 3 per cent, a refund shall be made to the consumer for the excess for a period equal to one-half of elapsed time since the last previous test, but not to exceed six months.

When a meter is slower than 3 per cent, the utility may charge consumer for the kilowatt-hours incorrectly metered for one-half of the time elapsed since the last test; such period not to exceed six months.

If the meter does not run, the utility may estimate the amount used by reference to previous periods and render bill to consumer.

Connecticut

Rule 6—When a meter is faster than the prescribed limits, the utility shall refund to the consumer the excess of the bills for the past six months, unless it can be found that the error existed for a greater or lesser period, in which case refund shall cover that period.

District of Columbia

Rule 10-a—The electric company shall make an adjustment for all meters registering fast in excess of 4 per cent; the adjustment to be based on the three previous months' bills.

Illinois

Rule 17—If a meter is found faster on any test than 4 per cent, the utility shall refund any overcharge during six months previous or the length of time since installation if it be less than six months, unless inaccuracy can be definitely determined to be for another period.

If meter is found slower than 4 per cent, the utility may, with certain limitations, render bill to the consumer covering the estimated consumption which had not been registered during the previous six months.

If meter is found creeping, an estimate of the amount shall be made and a refund granted.

If a demand meter shows more than 4 per cent error, an adjustment of charges is made, the same as for service meters. The error of the demand meter shall be determined in conjunction with the accuracy of the watt-hour meter when the demand meter is actuated by the watt-hour meter.

Indiana

Rule 19—If on any test a meter is found faster than 4 per cent, the excess charged for a period equal to one-half the time elapsed since the last test, but not to exceed six months, shall be refunded to the consumer.

If a meter is found slower than 4 per cent, the utility may charge consumer for the kilowatt-hours incorrectly metered for one-half the time elapsed since the last test, but not to exceed six months.

If meter is found not registering, the utility may estimate the amount used from previous billing period and charge consumer; such action to be taken only in cases of substantial importance where the utility is not at fault in the use of defective meter.

Massachusetts

Section 120—The refund shall be such amount as, if not agreed upon, shall be determined by the Department upon the customer's application and after opportunity is given the vendor to be heard.

Michigan

Rule 53—When meters are found more than 4 per cent fast, the utility shall refund an amount equal to the excess for the time the error actually existed, or for one-half the time elapsed since the last test, but not to exceed six months.

When meters are more than 4 per cent slow, the utility may bill consumer an amount equal to the loss, for the time the error actually existed, or for one-half the time elapsed since the last previous test, but not to exceed six months.

If meter is found not registering, the utility may estimate the amount used from previous bills and charge the consumer, in cases where a substantial amount is involved and where the utility is not at fault, for allowing the incorrect meter to be in service. No part of a minimum service or demand charge incorrectly measured need be refunded.

Missouri

Rule 31—A meter found in service registering within 4 per cent of correct registration, when tested in accordance with Rule 29, will be regarded as recording within allowable limits.

Montana

Rule 26—When meters are found more than 4 per cent fast, a refund shall be made to the consumer for the excess charged for a period equal to one-half the time elapsed since the last test, but not to exceed six months.

When meters are found more than 4 per cent slow, the utility may charge consumer for the kilowatt-hours incorrectly metered for one-half the time elapsed since the last test, but not to exceed six months.

If a meter is found not registering, the utility shall estimate the amount used from previous bills and charge consumer.

New Hampshire

Rule 8—If a meter is over 4 per cent fast, the utility shall refund to the consumer the excess charged for the previous six months.

If meter is more than 4 per cent slow, the utility shall apply to the Commission for the authority to bill consumer for the electricity used for previous six months.

New Jersey

Rule XXII—When a meter is found more than 4 per cent slow, a refund shall be made to the consumer as follows:

1st—If the date meter first became incorrect can be definitely ascertained, the refund shall be the excess charged for that entire period.

2nd—In all other cases the refund shall be the excess charged during one-half the time elapsed since the last test.

North Dakota

Rule 19—When meters are found more than 4 per cent fast, a refund shall be made to the consumer for the excess charged for a period equal to one-half the time elapsed since the last test but not to exceed three months.

When meters are found more than 4 per cent slow, the utility may charge consumer for the kilowatt-hours incorrectly metered for one-half the time elapsed since the last test, but not to exceed three months.

If a meter is found not registering, the utility shall estimate the amount used from previous bills and charge consumer.

Oklahoma

Rule 36—If a meter is found more than 3 per cent fast, a refund shall be made to the consumer for the excess charged for a period equal to one-half the time elapsed since the last previous test, but not to exceed six months.

If a meter is found more than 3 per cent slow, the utility may charge consumer for the kilowatt-hours incorrectly metered for one-half the time elapsed since the last test, but not to exceed six months, only if excess is more than $0.50.

If a meter is found not registering, the utility may estimate the amount used from previous bills and charge the consumer.

If a meter is found creeping, the utility should estimate the amount used and refund to the consumer.

Oregon

Rule 6-a—When a meter is found more than 4 per cent fast, a refund of the excess shall be made for a period of three months.

Rule 6-b—If a meter does not register at all, or registers less than 50 per cent, an average bill may be rendered, subject to review by the Commission.

Pennsylvania

Rule XXIV—If a meter is found more than 4 per cent fast, the utility shall refund or allow consumer an amount equal to the excess charged from the date of test through entire period of current bill, or to date of trouble when exact time is known.

South Carolina

Rule 18—If a meter is found more than 4 per cent fast, a refund shall be made to the consumer for the excess charged for a period of 60 days and not exceeding 60 days.

If a meter is found more than 4 per cent slow, the utility may collect from the consumer the amount estimated to be due for a period not to exceed 60 days.

West Virginia

Rule 9—When the average error of a meter is more than 2 per cent fast, the utility shall re-calculate the monthly bills for a period equal to one-half the time elapsed since the last test, but it shall not exceed three months, and the excess shall be refunded to the consumer.

When a meter is found more than 2 per cent slow, the utility may re-calculate the monthly bill for a period equal to one-half the time elapsed since the last test but not more than three months, and collect the difference from the consumer.

Testing Fees

California

Rule 15—The following fees shall be charged for request tests if more often than every six months, and the monthly bills are less than $150.00:

Meters up to and including 10 amperes	$1.00
Meters 15 amperes to 25 amperes, inclusive	2.00
Meters over 50 amperes	3.00
Meters with transformers	5.00

If the meter is found to be more than 2 per cent fast or slow, the entire fee shall be refunded.

Colorado

Rule 39—For tests by the Commission the following fee shall accompany application and shall be refunded to the consumer by the utility, if the meter is found to be faster than the prescribed limits:

Single-phase and direct-current meters not over 600 volts and 25 amperes	$2.00
For each additional 50 amperes or fraction thereof	.50
Single-phase meters over 600 volts and polyphase meters not over 25 kw	3.00
For each additional 25 kw	3.00

Connecticut

Rule 5—For Commission tests $1.00 shall accompany petition. If the meter is found to be more than 4 per cent fast the utility will refund said fee to the petitioner.

District of Columiba

Rule 12—The following fee shall be charged for referee tests:

Meters less than 50 amperes	$1.00
All other types	2.00

If a meter is found more than 4 per cent fast at any of light, normal or full loads, the above fee deposited by the consumer will be returned, and the fee shall be paid by the utility owning the meter.

Idaho

If the variation does not exceed 3 per cent the expense of a referee test is borne in some cases by the consumer. If the variation exceeds 3 per cent fast, the expense is borne by the utility.

Illinois

Rule 16—For tests made by the Commission, the following fee shall accompany the application and shall be refunded to the customer by the utility if the meter is found more than 4 per cent fast:

Single-phase or direct-current meters not over 25 amperes and 650 volts	$2.00
For each 50 amperes additional	.50
Single-phase meters above 650 volts and polyphase meters not over 25 kv-a	3.00
For each additional 25 kv-a	.50

The fee for a demand meter test shall be $2.00, to be refunded by the utility if the indicator over-registers more than 4 per cent. No meter shall be disturbed by the utility after notice of application for referee test, unless written authority of consumer or Commission is obtained.

Indiana

Rule 17—For tests by the Commission $2.00 shall accompany the application and shall be refunded to the consumer if the meter is found faster than the allowable limit, and collected from the utility.

Fee for a demand meter test shall be $10 and shall accompany application. Fee shall be refunded to the consumer if the demand is less than fixed by the utility. The amount shall then be collected from the utility.

Maryland

Rule 5-b—For tests by the Commission $1.00 shall accompany the application. If the meter is more than 4 per cent fast, the deposit will be refunded to the consumer and collected from the utility.

Michigan

Rule 51—For tests by the Commission $5.00 shall accompany the application and shall be refunded to the customer and collected from the utility if the meter is found faster than the prescribed limits.

Missouri

Rule 34—The following fee shall be charged for tests made at the Missouri State University:

Single-phase and direct-current meters not over 25 amperes and without instrument transformers	$2.00
For other sizes a proportionately larger fee will be charged.	

If the meter is found fast, the utility will pay the fee plus cost of shipping meter, otherwise such expenses shall be borne by the consumer.

Montana

Rule 25-b—For tests by the Commission $2.00 shall accompany the application. If the meter is found faster than the allowable limit, the fee will be refunded to the consumer and collected from the utility.

New Hampshire

Rule 6—For tests by the Commission $1.00 shall accompany the application. This fee shall cover the test of a meter not over 250 volts and 25 amperes; all other sizes shall have a fee as stated by the Commission. This fee shall be refunded to the consumer and collected from the utility if the meter is found more than 4 per cent fast.

Rule 7—The Commission will test periodically any meters it desires and charge utility $0.50 for the rating given in the above rule.

New Jersey

Rule XXVI—For tests by the Commission $1.00 shall accompany the application and shall be refunded to the consumer and collected from the utility if the meter is found faster than the prescribed limits. The meter shall be opened and sealed by a representative of the utility.

New York

Public Service Commission Law 1910—*Chapter* 480

SCALE OF FEES FOR TESTING METERS

Amperes Rated Capacity	Fee
5 and 10	$1.50
15	2.00
20 and 25	2.50
30, 40 and 50	3.00
60 and 75	3.50
100	4.00

For each additional 25 amperes or fraction thereof, 50 cents.

Public Service Commission Law 1910—*Section* 67

If the meter tested is found to be more than 4 per cent in error, to the prejudice of the consumer, the expense shall be borne by the corporation or the municipality; otherwise the consumer shall bear the expense.

North Dakota

Rule 17-a—For tests by the Commission $5.00 shall accompany the application. If the meter is found faster than the allowable limit, the fee shall be refunded to the consumer and collected from the utility.

Oklahoma

Rule 19-a—The following fee shall be charged for tests made by the Commission:

Single-phase and direct-current meters not over 650 volts and 25 amperes	$2.00
For each additional 50 amperes	.50
Single-phase meters over 650 volts and polyphase meters not over 25 kv-a	3.00
For each additional 25 kv-a	.50

If the meter is found more than 3 per cent fast, average error, the fee will be refunded to the consumer and collected from the utility owning the meter.

Oregon

Rule 23—The following fees are to be deposited when tests are made by the Commission and are to be returned to the consumer and paid by the utility if the meter is found more than 4 per cent fast.

Meters up to 250 volts, 50 amperes	$2.00
Meters up to 100 amperes	4.00
All other meters	8.00

Pennsylvania

Rule XVIII—The following fee shall be charged for tests by the Commission to be paid by the consumer to the Commission if meter is correct, and borne by the utility if the meter is found incorrect.

Single-phase or direct-current meters not over 25 amperes or 600 volts	$1.50
For each additional 50 amperes or fraction thereof.	.50
Single-phase meters over 600 volts and polyphase meters not over 25 kw	2.50
For each additional 25 kw. or fraction thereof	2.50

South Carolina

Rule 17—There will be no charge for request tests except when the test is more often than six months or the consumer's monthly bill is less than $25.00, in which case the following fee will be charged if meter is less than 3 per cent fast:

Single-phase and direct-current meters up to 600 volts and not over 25 amperes	$1.50
Each additional 50 amperes or fraction thereof	.50
Single-phase meters over 600 volts and polyphase meters not over 25 kw	2.50
For each additional 25 kw	2.50

West Virginia

Rule 28-b—The following fee shall be charged for inspections by the Commission and shall be borne by the utility if the meter is found more than 2 per cent fast:

Single-phase and direct-current meters under 250 volts; up to and including 30 amperes	$1.50
30 amperes up to and including 100 amperes	3.00
For each additional 50 amperes or fraction	.75

Polyphase and single-phase or direct-current meters over 250 volts:

5 kw. and under	$1.00
5 kw. to 25 kw.	2.00
25 kw. to 100 kw.	6.00
100 kw. to 500 kw.	15.00
Over 500 kw.	30.00

Wisconsin

Rule 21—For referee tests the following fee shall accompany the application and shall be refunded to the consumer by the utility if the meter is found more than 4 per cent fast:

Single-phase and direct-current meters not over 250 volts and 25 amperes	$2.00
All others not exceeding 100 amperes	4.00
All other capacities	8.00

NEW DEVELOPMENTS
in
ELECTRICAL MEASURING DEVICES

The purpose of the following report on New Developments in Electrical Measuring Devices is to bring to the attention of those interested the results of a recent survey made by the Meter Committee.

No attempt has been made to verify the claims made for the devices described. Therefore, the Committee does not officially approve the various devices, but submits this material as worthy of consideration and investigation.

Single-Phase Watthour Meters

The accuracy of energy measurements has received attention consistent with its important place in the industry. The last few years have shown marked changes in the design of all American watthour meters. The efforts of the Meter Committee, N. E. L. A., to standardize terminal chambers and connections, as to size and position as outlined in Publication No. 278-16, are reflected in the announcements made here by the manufacturers. As to accuracy, the improvements have been along the lines of improved overload accuracy, temperature compensation, voltage variation and other electrical characteristics.

Type MD, Single-Phase, Watthour Meter Made by the Duncan Electric Manufacturing Co.

The Duncan Electric Manufacturing Co. has placed on the market an improved watthour meter known as the Type MD. It supersedes the Type M2 and is available in sizes from 5 to 75 amperes, inclusive. The external appearance of the Type MD meter is somewhat similar to that of the Type M2, differing only in the design of the nameplate and the terminal chamber. In the 5 to 25-ampere sizes the terminal chamber cover is die-cast and is so arranged that it may be swung down to give access to the terminals, or be removed entirely. Recently the design of the terminal chamber sealing screw was modified so as to permit the use of the lead, padlock, or ribbon type seal. This sealing screw, shown in Fig. 1, is loosened by the fingers in the same manner as a wingnut.

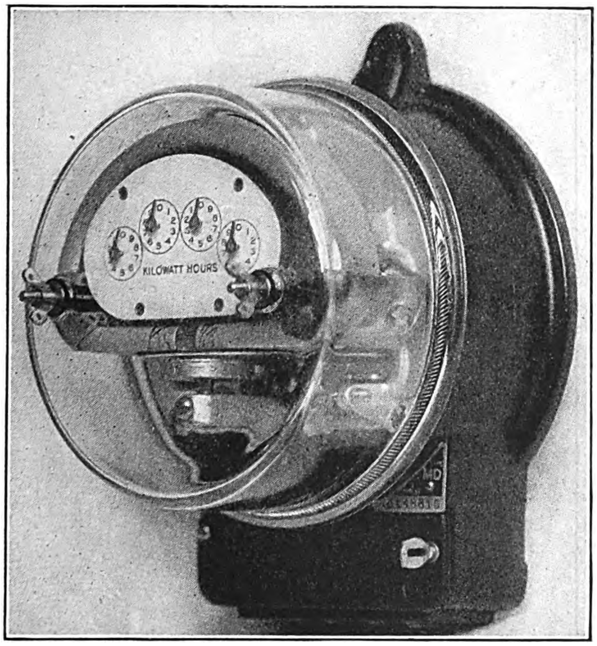

FIG. 1—TYPE MD, 5-AMPERE, SINGLE-PHASE WATTHOUR METER MADE BY THE DUNCAN ELECTRIC MANUFACTURING COMPANY.

In the 5 to 25-ampere sizes the potential and current electro-magnets are mounted on a sub-base, which is dowelled to the meter base as a unit, thus giving better accessibility for repairs. The manufacturer claims that the refinements in the design of the electro-magnets, and the reduction of the full load speed, gives the Type MD meter better performance characteristics than the Type M2 meter. The manufacturer further advises that in the near future the Type MD meter will be compensated for errors due to changes in ambient temperature, this compensation being equally effective at all power factors.

The base of the new 50 and 75-ampere meter, shown in Fig. 2, is a casting. The terminal chamber is designed to comply with the standards agreed upon by the Meter Manufacturers and the N. E. L. A. Meter Committee. In these sizes, as well as in the smaller sizes, the nameplates containing the meter rating, serial number, etc., are two small triangular shaped plates, riveted securely to the base, so as not to be disturbed by the removal of the terminal chamber cover. These sizes have the same full load speed as the 5 to 25-ampere sizes and similar characteristics.

Type I-16, Single-Phase, Watthour Meter Made by The General Electric Co.

The Type I-16 single-phase meter has superseded the Type I-14. It is characterized by its improved overload accuracy and refinement in mechanical design. Both two and three-wire meters of sizes up to and including 50 amperes are available. The meter is normally furnished for use at 60 cycles, but can also be furnished for 40 cycles. Since the improved load characteristics warrant their use on overloads, the series coils are designed to carry at least four times rated current. Two sizes of base

---

Publication No. 289-47, Serial Report, Meter Committee.

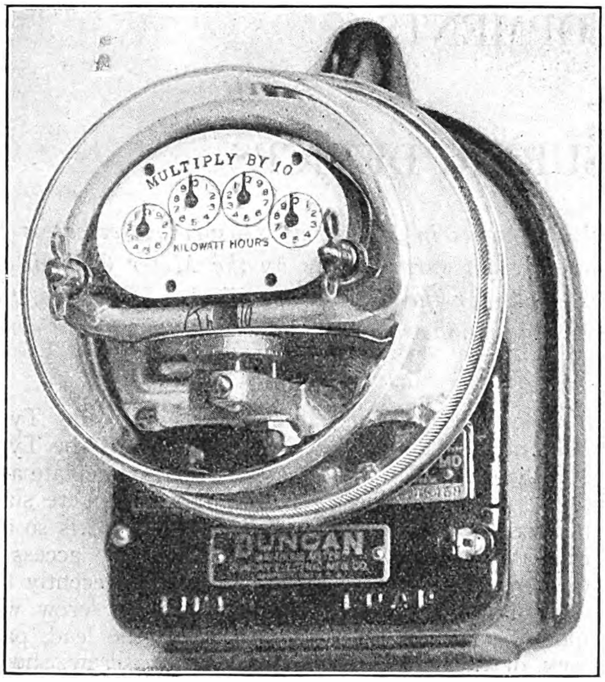

FIG. 2—TYPE MD, 75-AMPERE, SINGLE-PHASE WATTHOUR METER MADE BY THE DUNCAN ELECTRIC MANUFACTURING COMPANY.

are used, one for the 5 and 10-ampere meters, and the other for the 15, 25 and 50-ampere meters.

The cover is made of glass and has attached to its edge a tight fitting steel flange. This flange fits snugly around the meter base, and a slight twist locks it in place, making a dust and tamper-proof joint. The cover is thus fastened without the aid of sealing pins, wingnuts and washers. The terminal chamber cover is removable, but will not fall off. The meter cover and terminal chamber cover may be sealed separately, or a single seal may be used to seal both. Any commonly used type of seal may be used.

The manufacturer makes the following claims for the new electrical element:

1. Rigid mechanical construction
2. Large air gaps
3. Accessibility
4. Removable as a unit
5. Improved electrical performance.

A new magnet with high damping strength is used, and the meter operates at reduced speed. A micrometer full load adjustment moves the damping magnet bodily. A simple micrometer adjusting device, without clamping screws and accessible from the front, gives ample range of adjustment on light load. A lag adjustment is also provided.

The manufacturer claims high accuracy on overloads without any sacrifice in torque, thus insuring equally good accuracy at light loads. All meters are compensated for a temperature range of zero to 100 deg. fahr.

The terminals and bushings of the 5 and 10-ampere sizes are separate and removable; for the 15 to 50-ampere sizes they are assembled in a molded block. The potential test loop is omitted from the two-wire meters. Fig. 3 shows a 5-ampere, 110-volt Type I-16 meter.

Type HC, Single-Phase, Watthour Meter Made by The Sangamo Electric Co.

The Sangamo Electric Co. announces a new type of single-phase watthour meter known as the Type HC. In size, shape, appearance and general construction, it is the same as the Type H, but has improved performance. Aside from slight modifications, the electrical and magnetic circuits are the same as those of the Type H. Important parts, such as the full load and light load adjustments, etc., are interchangeable with those of the Type H, thus eliminating the necessity of adding to the stock of repair parts now on hand.

The manufacturer states that the outstanding changes and improvements in the Type HC may be listed under the following headings:

1. Complete temperature compensation on both inductive and non-inductive loads from 20 to 120 deg. fahr. There is no appreciable variation in accuracy at any power factor for the same temperature range.
2. Straight line accuracy characteristic up to 300 per cent of rated load.
3. The speed of the 60-cycle meter has been decreased so that both 25 and 60-cycle meters have the same disc constant, viz: 1200 watt-seconds for the 5-ampere, 110-volt meter.
4. Direction of rotation has been reversed for the purpose of standardization.
5. The metal cover is stiffer. This added rigidity is obtained by reinforcing the ribs around the studs and around the disc opening.

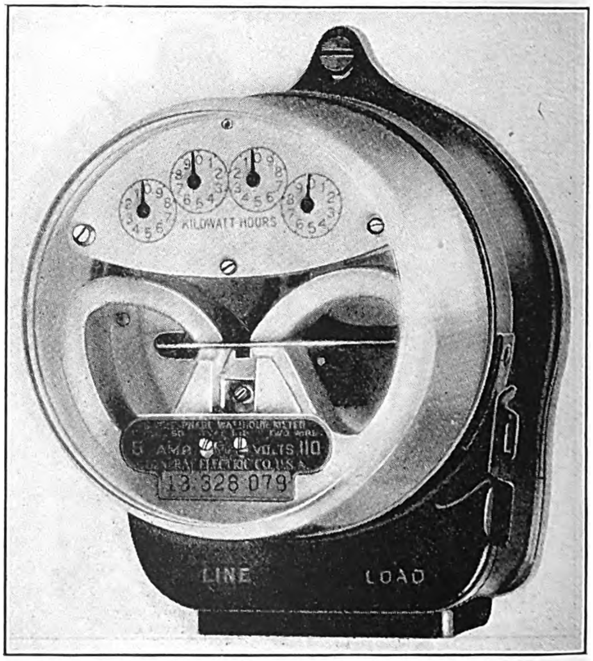

FIG. 3—TYPE I-16, SINGLE-PHASE, WATTHOUR METER MADE BY THE GENERAL ELECTRIC COMPANY.

6. Each permanent magnet is fitted with a flat clamp or locator, which is firmly swaged to the bottom of the magnet. The locator fits over two dowel pins in the grid, the magnet being accurately and positively fixed in position.
7. Although a slight increase has been made in the thickness of the disc, the weight of the moving system remains the same. This is accomplished by making the hub and spindle of duralumin.

Fig. 4 shows the Type HC watthour meter with cover and terminal cover plate removed.

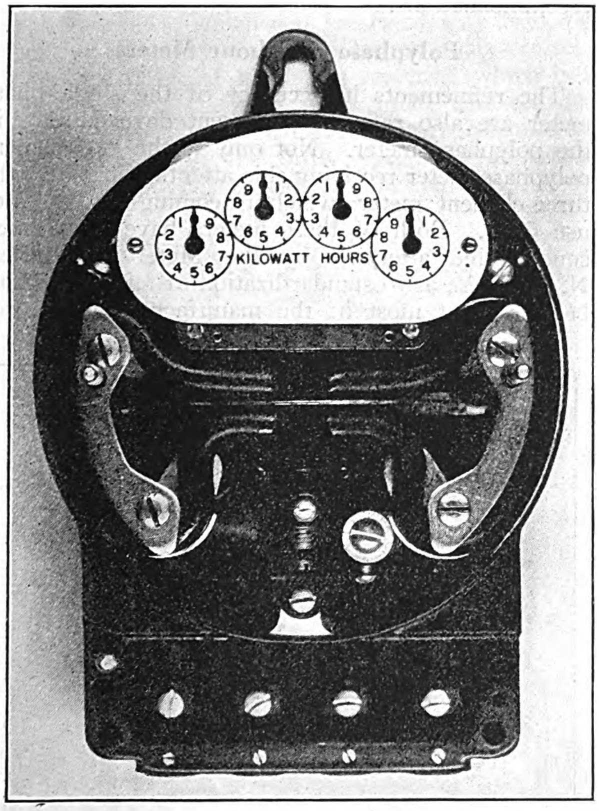

FIG. 4—TYPE HC, SINGLE-PHASE, WATTHOUR METER MADE BY THE SANGAMO ELECTRIC COMPANY—METER COVER AND TERMINAL CHAMBER COVER REMOVED.

Type OB, Single-Phase, Watthour Meter Made by The Westinghouse Electric & Manufacturing Co.

The Westinghouse Electric & Manufacturing Co. announces that it has made some marked improvements in the overload performance of its Type OB meters, previously reported. It is claimed that by making slight internal changes in the electromagnet, the accuracy characteristic has been made practically a straight line from light load to beyond 200 per cent of rated load. The characteristic watthour meter accuracy curve below full load has been retained, and other characteristics of the meter remain the same. The changes do not in any way affect the interchangeability of parts. The manufacturer also claims that the single-phase Type OB meters are now compensated for temperature errors.

The switchboard watthour meters using the Type OB element are available in both the single and polyphase forms. The single-phase meter is the same as the single-phase Type OB house service meter, with the exception that it does not have a terminal chamber. These switchboard meters are rear connected and are supplied with terminal studs which are suitable for steel panel or 2 in. slate panel mounting. The diameter of the single-phase meter is approximately 5 in. Fig. 5 shows a Type OB single-phase switchboard meter.

Two-Element, Three-Wire, Watthour Meters

The two-element, three-wire watthour meter has been developed to measure energy taken from two phases and the grounded neutral of a three-phase four-wire system. This meter also lends itself to the accurate measurement of three-wire, single-phase service, under conditions of unbalanced voltages and loads.

To meet this demand and to comply with the requirements of the user in respect to meter size and cost, the meter manufacturers have placed upon the market special two-element, three-wire meters.

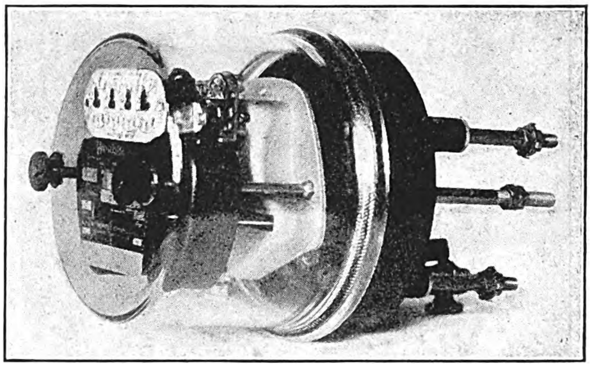

FIG. 5—TYPE OB, SINGLE-PHASE, WATTHOUR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

Type I-18, Two-Element, Three-Wire, Watthour Meter Made by The General Electric Co.

A new two-element, three-wire meter, designated as Type I-18, is shown in Fig. 6. It is intended for metering three-wire service obtained from two-phases and neutral of a four-wire, three-phase system.

It consists of two single-phase I-16 meter elements mounted in one case. Its design features and performance characteristics agree in practically every detail with those of the single-phase Type I-16 meter. Certain new features, such as the cover locking and sealing device, are shown in Fig. 7. This meter has an improved element balancing micrometer adjustment. It is furnished in 5, 10, 15 and 25-ampere sizes.

Type HC, Two-Element, Three-Wire, Watthour Meter Made by The Sangamo Electric Co.

The Type HC is a bottom-connected, two-element, three-wire meter, having a terminal chamber of the

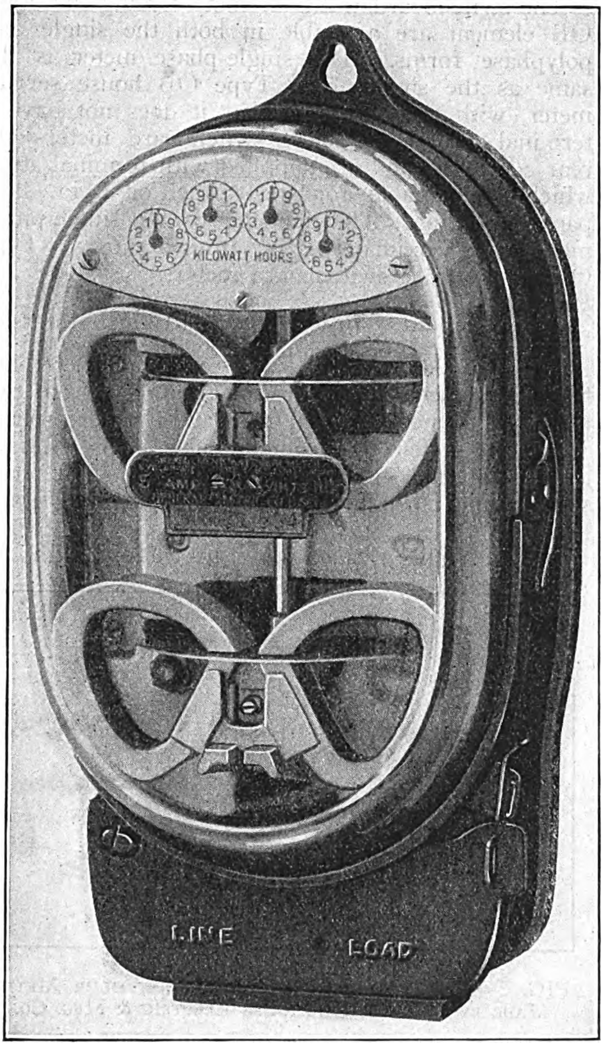

FIG. 6—TYPE I-18, TWO-ELEMENT, THREE-WIRE, WATTHOUR METER MADE BY THE GENERAL ELECTRIC COMPANY.

same dimensions as the corresponding two and three-wire single-phase meters. A base of a certain size is used for the 5 and 10-ampere meters, and a larger base is used for the 15 and 25-ampere meters. The dimensions are in agreement with the recommendations of the Meter Committee, N. E. L. A. on standardization of terminal chambers. Removable terminals are used.

This meter has the latest improvements of the HC type and is claimed to be fully compensated for temperature changes between 20 and 120 deg. fahr. The same full load, light load, inductive load and element balancing adjustments which are used in the polyphase meter are used in the new type meter. Parts will be partially interchangeable. This meter is shown in Fig. 8.

Type OB, Two-Element, Three-Wire, Watthour Meter Made by The Westinghouse Electric & Manufacturing Co.

Fig. 9 shows a two-element three-wire meter built by the Westinghouse Electric & Manufacturing Co., for metering energy taken from two phases and the grounded neutral of a three-phase four-wire system. It has two OB single-phase elements which drive two discs on a common shaft, and is designed to have the same accuracy, performance characteristics and adjustments as the single-phase Type OB meter, with the exception that each electro-magnet is provided with a micrometer phase balancing adjustment, such as used in the Type OB polyphase meter.

The base is made of cast iron. The terminal chamber is located at the bottom of the instrument to conform with Meter Committee, N. E. L. A., recommendations.

Polyphase Watthour Meters

The refinements in accuracy of the single-phase meter are also reflected in recent developments in the polyphase meter. Not only is the two-element polyphase meter receiving this attention, but also the three-element meter, which is coming into greater use daily. Both of these meters have been given considerable attention by the Meter Committee, N. E. L. A., as to standardization of terminal chambers, so that most of the manufacturers are pro-

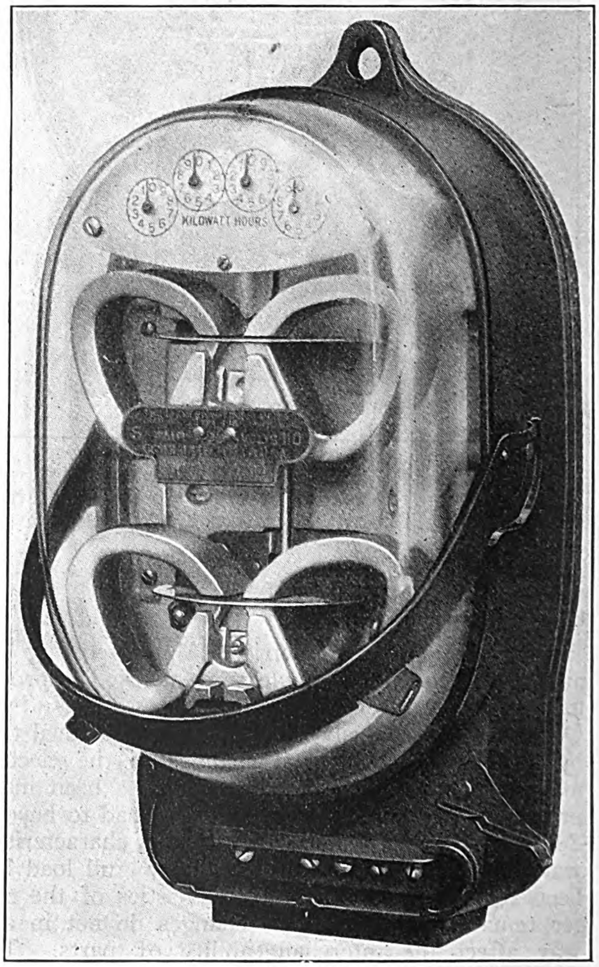

FIG. 7—TYPE I-18, TWO-ELEMENT, THREE-WIRE, WATTHOUR METER—SHOWING DETAILS OF COVER FASTENING DEVICE.

ducing bottom-connected polyphase meters of standard design.

Type MD, Polyphase, Watthour Meter Made by The Duncan Electric Manufacturing Co.

The Type MD polyphase watthour meter was shown to the Meter Committee at the October, 1928, meeting. It is expected that this meter will be in full production some time during the winter. It is of the bottom-connected type, as shown in Fig. 10. The base is a casting, designed in accordance with N. E. L. A. specifications. The terminal chamber cover is also cast and is held in place with two sealing screws, which can be sealed with lead, padlock, or ribbon type seals. The terminals are set in a molded block of insulating material, which is removable from the base as a unit. The terminals are also individually removable for replacement and and arranged in the order specified for bottom-connected polyphase meters. The nameplate is similar to that used on the Type MD single-phase meter, consisting of two triangular plates, bearing the rating, serial number, etc. The two pieces are fastened to the base and are not disturbed by the removal of the terminal chamber cover.

WESTINGHOUSE ELECTRIC & MFG. CO.

FIG. 9—TYPE OB, TWO-ELEMENT, THREE-WIRE WATTHOUR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

The arrangement of the electro-magnets is similar to that of the Type M2P, the preceding type of polyphase meter made by this company, but the leads are fastened to anchoring blocks on each side of the base. From these blocks the leads run to the terminal chamber. The register mechanism, the adjustments and bearings, are the same as in the Type M2P meter.

The manufacturer claims that the meter will be compensated for temperature errors at all power factors.

The single-phase Type MD meter constants will be applicable to the polyphase meter. Self-contained meters of this type will be supplied with current ratings of from 5 to 75 amperes, and voltage ratings of 115, 230 and 460 volts.

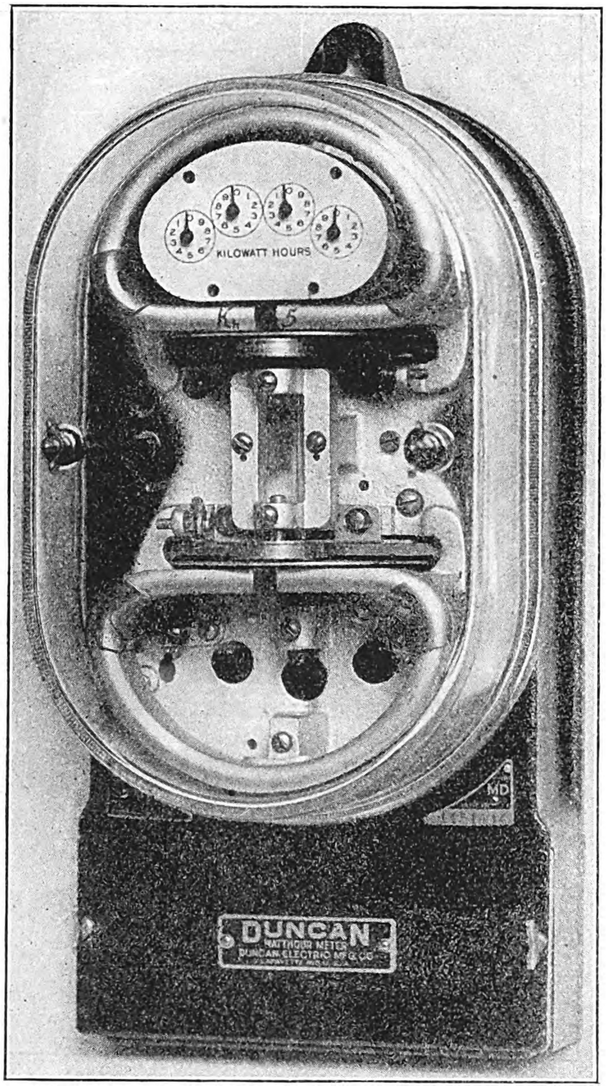

FIG. 10—TYPE MD, TWO-ELEMENT, POLYPHASE WATTHOUR METER MADE BY THE DUNCAN ELECTRIC MANUFACTURING COMPANY.

Types D-14 and D-15 Polyphase, Watthour Meters Made by The General Electric Co.

The General Electric Co. now has in production a new line of bottom-connected polyphase meters, identified as Type D-14 and Type D-15. The Type D-14 meter, shown in Fig. 11, has two elements, while the Type D-15 meter, shown in Fig. 12, has three elements. They supersede the Types D-7 and D-9, and embody all the essential characteristics of the Type I-16 meter, together with some additional features. They are built in sizes of 5, 10, 15, 25 and 50 amperes. As in the Types I-16 and I-18, the base and frame are in one piece, and the meters are provided with a back cover plate. The molded glass cover with steel flange and gasket is held in place by the same novel type of clamp used in Type I-18 meters. The arrangement of terminals and the overall dimensions of the terminal chamber conform to standard practice. The 5 and 10-ampere terminals are inclosed in separate replaceable bushings. The 15- to 50-ampere sizes have a single molded terminal block.

All adjustments, full load, light load, power factor, and balance of elements, are of the micrometer type, accessible from the front of the meter. Potential indicator lamps, for detecting an open potential circuit, are furnished when specified.

The use of the I-16 element provides the same range of accuracy, overload rating and high torque found in that meter. The manufacturer advises that wide temperature changes have no effect on the accuracy of this meter on any load or power factor, as it is completely compensated for temperature. Fig. 13 shows a rear view of the Type D-14 meter with back cover plate removed.

Type HC Polyphase Watthour Meter Made by The Sangamo Electric Co.

The vertical polyphase meter is being modified so that it will be bottom-connected and will have standard dimensions as recommended by the Meter Com-

mittee, N. E. L. A. Removable terminals will be used, and the base will be the same for all capacities. Fig. 14 shows the Type HC vertical, bottom-connected, two-element, polyphase watthour meter.

Type OB Polyphase, Watthour Meter Made by The Westinghouse Electric & Manufacturing Co.

The Type OB polyphase meters are manufactured in both the two- and three-element types, Fig. 15 and 16, respectively. They are bottom-connected and have standard terminal chambers. The base and terminal assembly consists of iron castings somewhat similar to those used in former designs, with the exception that the terminal chamber is at the bottom. The covers are made of glass and are rectangular in shape. The meter is mounted on the wall or the support with two screws, similar to the manner of mounting the single-phase Type OB meter.

The micrometer adjustments are the same as those of the single-phase meter. The adjustment for balance between elements is made by means of a micrometer screw which shifts a plate in the laminations under the disk. The individual meter elements are mounted on a common support so that the complete polyphase element may be removed from the base as a unit.

The polyphase Type OB switchboard meter is made in both the two and three-element forms. These meters are smaller than the corresponding house meter due to the elimination of the terminal chamber, Fig. 17 and 18.

Watthour Meters for Use With Instrument Transformers

Standard type current transformers designed to give 5 amperes secondary current at full load cannot be overloaded for any length of time without overheating. This makes it impossible to take advantage of the long range accuracy of the modern 5-ampere watthour meter. Therefore, a 2½-ampere, or the so-called "Instrument Transformer Watthour Meter," has been recently developed. With this type of meter accurate registration can be obtained from light load to 200 per cent of normal load of the meter, namely 5 amperes, which is the normal secondary current of the current transformer.

60 CYCLES

FIG. 15—TYPE OB, TWO-ELEMENT, POLYPHASE WATTHOUR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

This meter also makes possible the more accurate determination of the maximum demand. As the speed of the 2½-ampere meter is approximately twice that of the 5-ampere meter, the demand determination automatically becomes 100 per cent more accurate.

The General Electric Co. announces such a line of watthour meters. The increase in the number of turns of the current or series winding has doubled the torque without sacrifice in accuracy over the working range of the meter and current transformer combination. The disc speed is twice that of the self-contained meter, hence the test constant has been halved. The foregoing applies to the Types I-16, D-14 and D-15 meters. The Type I-18 is not furnished for use with instrument transformers.

The Westinghouse Electric & Manufacturing Co. also announces a similar line of instrument transformer meters, which can be obtained in either the house or switchboard types.

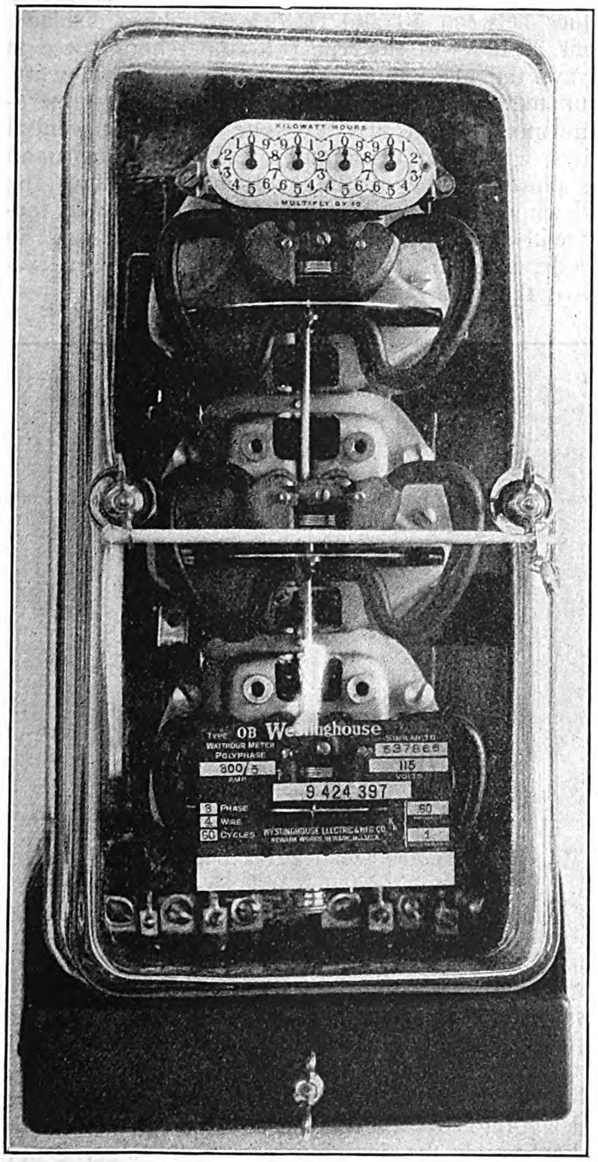

FIG. 16—TYPE OB, THREE-ELEMENT, POLYPHASE WATTHOUR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

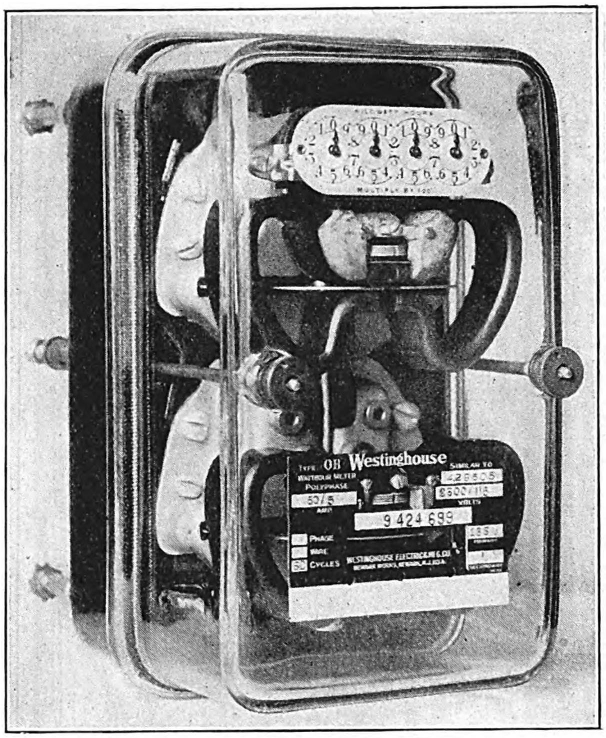

FIG. 17—TYPE OB, TWO-ELEMENT, POLYPHASE WATTHOUR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.—SWITCHBOARD TYPE.

Volt-Amperehour Meters

To encourage the consumer to improve the power factor of his electrical load, contracts have been offered by some utilities which base the charge on the volt-amperehour.

The Trivector Volt-Amperehour Meter Made by Landis & Gyr, Inc.

The new Trivector meter developed by Landis & Gyr, Inc., combines in one unit a watthour meter, a reactive volt-amperehour meter, and a special gear mechanism which the manufacturer claims is capable of computing the true volt-amperehours of a load regardless of power factor variations.

A watthour meter will register volt-amperehours within commercial accuracies over a range of 10 deg. phase variation, or from 0 to 10 deg. phase displacement, because the cosine of angles within this range vary only slightly. Likewise a reactive volt-amperehour meter will register correct volt-amperehours of a load varying from 80 deg. to 90 deg. in phase displacement, because the sine of angles within that range vary but slightly. The special gear mechanism of the Trivector meter is so constructed that during the periods in which the power factor falls within the limits mentioned above, the volt-amperehour dial is driven directly by the proper unit and registers the correct volt-amperehours. Referring to the schematic diagram, Fig.

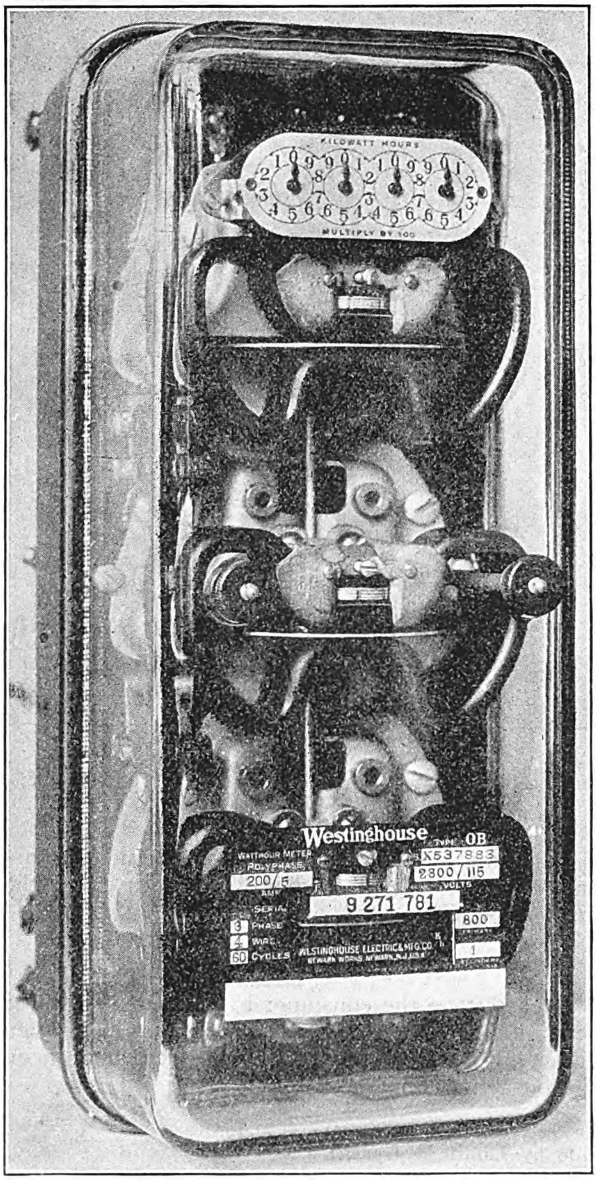

FIG. 18—TYPE OB, THREE-ELEMENT, POLYPHASE WATTHOUR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.—SWITCHBOARD TYPE.

19, the main shaft, 14, of the gear train of the watthour meter is geared to the volt-amperehour register through a ratchet, 18. In like manner the gear train shaft, 15, of the reactive volt-amperehour meter is connected to the main shaft of the volt-amperehour register, 30, through ratchet 18′. Due to the ratchet arrangement, the meter running at the greater speed actuates the volt-amperehour register. Besides being geared through ratchets to the volt-amperehour register, as already described, the watthour and the reactive volt-amperehour registers are coupled together through three sets of differential gears, shown at 19, 20 and 21 in Fig. 19. The resultant torque of each of these differential units is transmitted through a ratchet to the main volt-amperehour register shaft, 22. The gear ratios along the connecting linkage are so selected that the resultant speed of each will register true volt-amperehours for a separate range of power factor values between 10 and 80 deg. of phase displacement. Therefore, as true volt-amperehour speed is always the maximum speed, either the main watthour meter direct drive, the reactive volt-amperehour meter direct drive, or one of the differential drives will be at maximum speed, depending upon the power factor of the load, and will drive the volt-amperehour register. The value of power factor will always determine which gear train will do the driving, this factor varying as the power factor of the load varies.

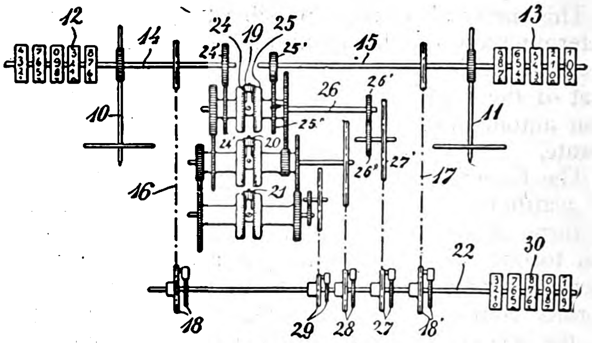

FIG. 19—SCHEMATIC DIAGRAM OF THE GEAR MECHANISM OF THE TRIVECTOR VOLT-AMPEREHOUR METER MADE BY LANDIS & GYR, INC.

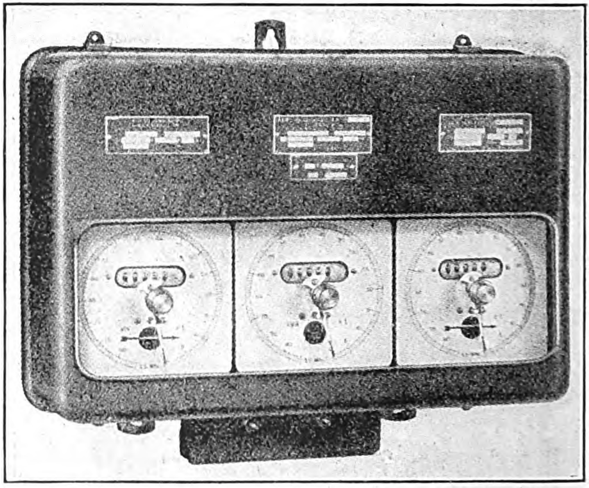

FIG. 20—TRIVECTOR VOLT-AMPEREHOUR METER MADE BY LANDIS & GYR, INC.

The meter shown in Fig. 20 will register volt-amperehours, watthours and reactive volt-amperehours, and the maximum demand of each. It is designed to register these only for a lagging power factor range of from unity to zero. However, with suitable modifications, it can be made to register the volt-amperehours for all power factors both leading and lagging. In the latter case two registers would make possible the distinguishing of the lagging and leading values separately. This meter is very flexible in its application. It is possible to modify it to furnish many combinations of registrations.

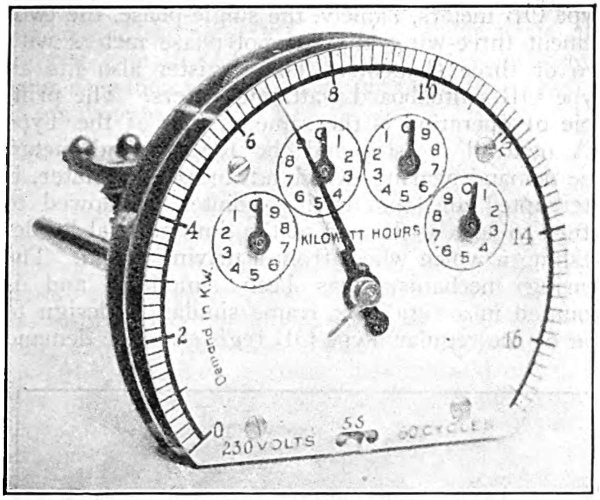

FIG. 21—DEMAND REGISTER MADE BY THE DUNCAN ELECTRIC MANUFACTURING CO.

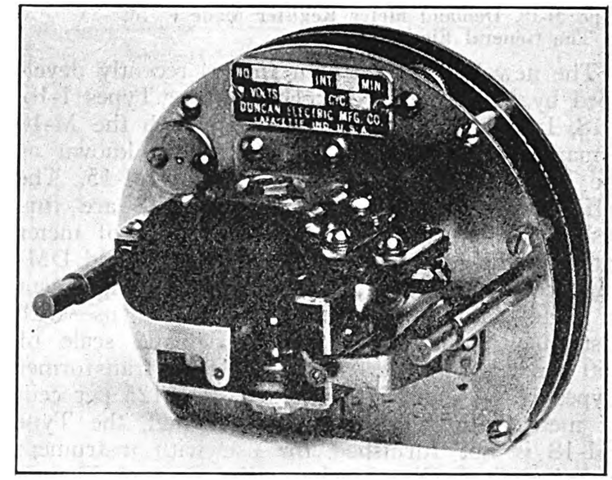

FIG. 22—DUNCAN DEMAND REGISTER—REAR VIEW.

Demand Registers

The demand registers of the various manufacturers have been remodeled to cover the working range of their new types of watthour meters, and to be mechanically applicable to all the various types manufactured by them.

Demand Register Made by The Duncan Electric Manufacturing Co.

The Duncan Electric Manufacturing Co. has recently announced some improvements in its block interval type of demand register. This register is similar to the one which it placed on the market about two years ago, differing only in a few details of mechanical design which provide more rugged construction and improved accuracy. The demand scales now supplied conform to the latest N. E. L. A. Meter Committee recommendations in regard to overloads. The demand scales are about 7¾ in. in length and occupy approximately 250 deg. of the dial face. The time interval is controlled by a small synchronous motor having a speed of 1200 r.p.m. Front and rear views of this register are shown in Fig. 21 and 22.

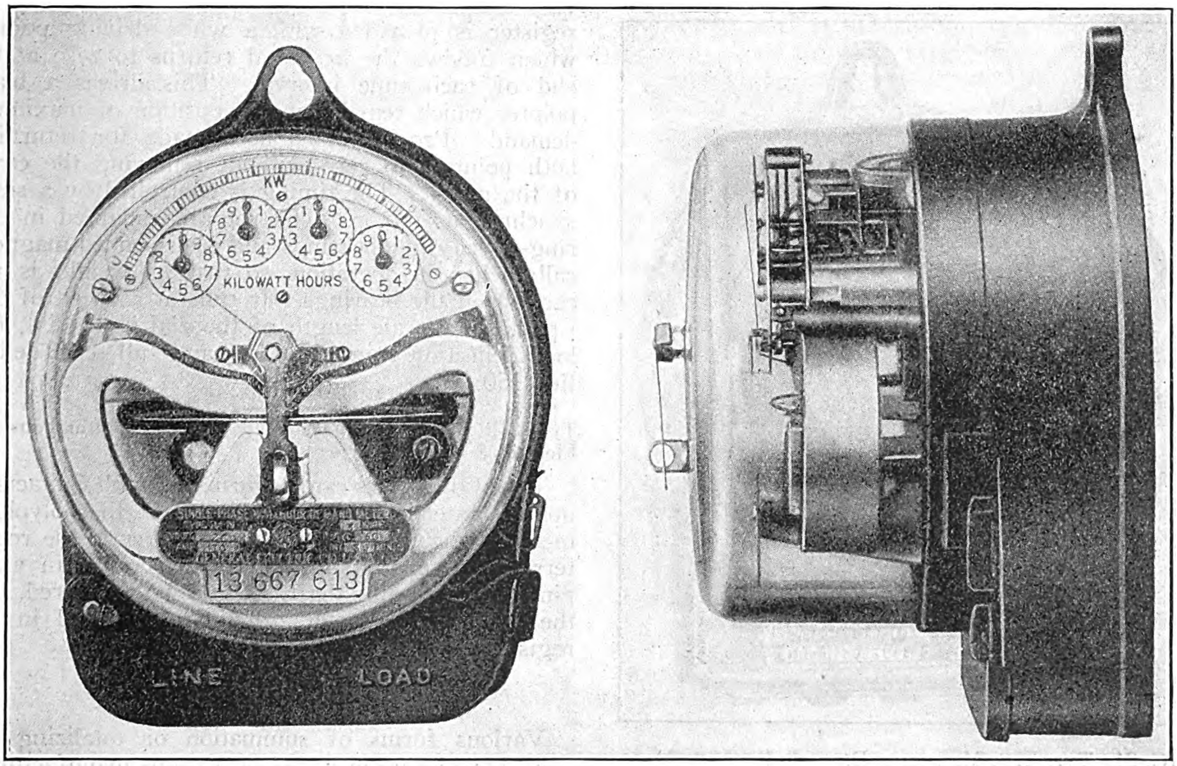

FIG. 23—TYPE IM-16 WATTHOUR DEMAND METER MADE BY THE GENERAL ELECTRIC COMPANY—FRONT AND SIDE VIEWS.

Type M-10, Demand Meter Register Made by The General Electric Co.

The new line of watthour meters recently developed by the General Electric Co., the Types I-16, I-18, D-14 and D-15, are available with the M-10 demand register equipment. They are known as the Types IM-16, IM-18, DM-14 and DM-15. The self-contained Types IM-16 and IM-18 are furnished with a full scale of 300 per cent of meter rating. The self-contained Types DM-14 and DM-15 have a full scale demand rating of 250 per cent of meter rating. The Type IM-16 for use with instrument transformers has a demand scale of 150 per cent of meter rating, while the transformer Types DM-14 and DM-15 scales are 125 per cent of meter rating. As previously stated, the Type IM-18 is not furnished for use with instrument transformers. Fig. 23 shows the General Electric Type IM-16 watthour demand meter.

Type HB Maximum Demand Register Made by The Sangamo Electric Co.

The Type HB demand attachment previously announced has been changed to meet the N. E. L. A. Meter Committee specification of a 300 per cent load value scale on a 300 deg. dial. Fig. 24 illustrates a Sangamo Type HC, single-phase watthour meter equipped with a Type HB maximum demand register.

Type OB Demand Registers Made by The Westinghouse Electric & Manufacturing Co.

The Type OB demand register shown in Fig. 25 is designed to fit the complete line of Westinghouse Type OB meters, namely, the single-phase, the two-element three-wire, and the polyphase meters with two or three elements. This register also fits all Type OB switchboard watthour meters. The principle of operation is the same as that of the Type OA demand register and the RA demand meter. The demand gearing, which advances the pointer, is interrupted and the driving pointer is allowed to return to zero at the end of the time interval by demeshing a worm wheel from a driving worm. The gearing mechanism has been simplified and is mounted in a rigid box frame similar in design to that of the regular Type OB register. The demand register is provided with a white driving pointer which follows the load and returns to zero at the end of each time interval. This drives a black pointer which remains in the position of maximum demand. Provision has been made for returning both pointers to zero without removing the cover of the meter. The timing is controlled by a small synchronous motor. The rotor is mounted in two ring-jewel guide-bearings and is suspended magnetically when in operation, so that its weight is not carried on the bearings. It runs at a speed of 600 r.p.m. The scale length of the dial is 3⅝ in., full load deflection being 120 deg. and full scale deflection 150 deg.

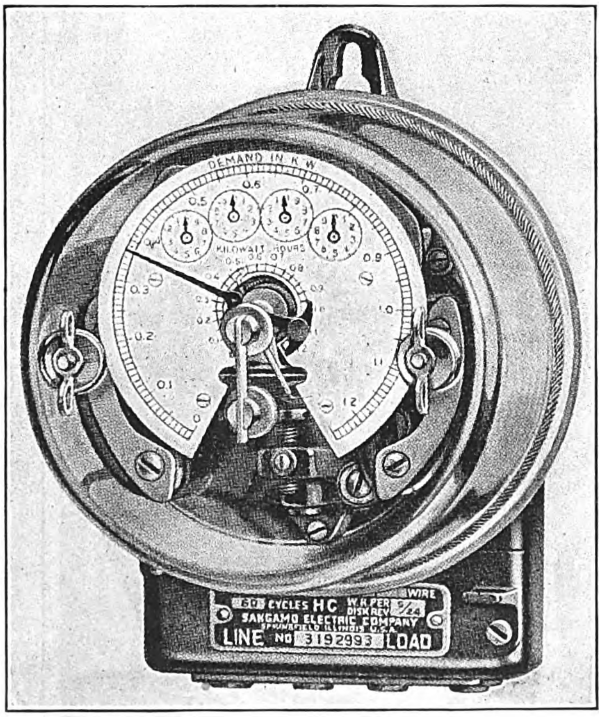

FIG. 24—TYPE HB, MAXIMUM DEMAND REGISTER MADE BY THE SANGAMO ELECTRIC COMPANY MOUNTED ON A TYPE HC SINGLE-PHASE WATTHOUR METER MADE BY THE SAME MANUFACTURER.

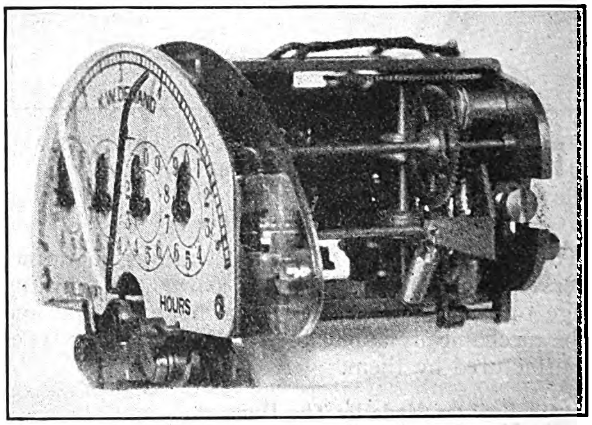

FIG. 25—TYPE OB, DEMAND REGISTER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.—SIDE VIEW, SHOWING DETAILS OF MECHANISM.

Type OB Demand Contacts Made by The Westinghouse Electric & Manufacturing Co.

Type OB meters can be furnished with contacts to operate external demand devices. In the polyphase meters the contacts are mounted either in the registers or in separate assemblies driven by an extra pinion on the disc shaft, as may be preferred. In the single-phase meters, they are mounted in the registers.

Load Totalizing Meters

Various forms of summation or totalizing devices have been developed by various manufacturers to measure the consumption on two or more independent circuits, and also to combine the maximum demands of these circuits. It is desirable to do this without complicating the metering equipment, endangering its accuracy, or unduly increasing the cost of maintenance.

Totalizing Meter Made by Landis & Gyr, Inc.

A meter for totalizing the readings of two independent circuits has been in production for a number of years by Landis & Gyr, Inc. The manufacturer claims that this device will measure the combined consumption of a three-phase, three-wire, and a three-phase, four-wire circuit, and will give the combined periodic maximum demand on these circuits. The record can be registered on a demand indicator or on a chart by adding the usual attachments in a manner similar to that done with watthour meters.

A device is needed to obtain the same data for a combination of more than two circuits, including both alternating-current and direct-current circuits. To meet this latter requirement, this company has developed a new totalizing device, which is now in production, and is illustrated in Fig. 26.

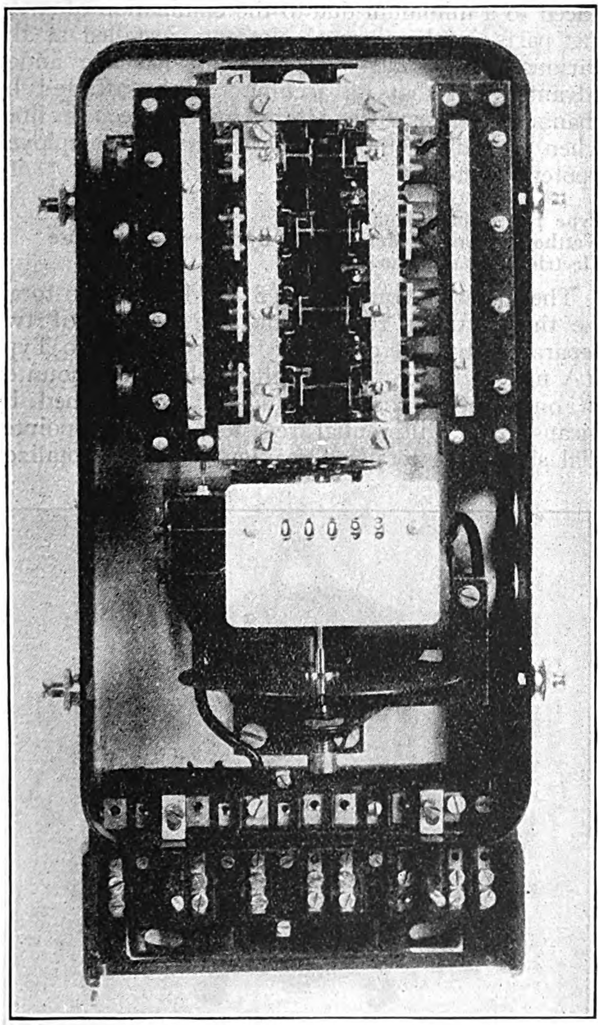

FIG. 26—TOTALIZING METER MADE BY LANDIS & GYR, INC.

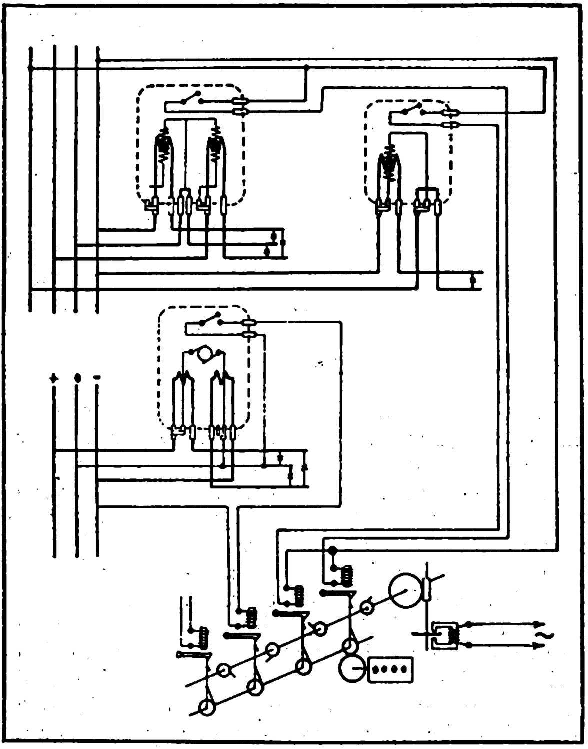

FIG. 27—SCHEMATIC DIAGRAM OF THE TOTALIZING METER MADE BY LANDIS & GYR, INC.

The principle of operation of this device is shown schematically in Fig. 27. Three circuits and corresponding meters are shown, namely, a polyphase circuit and its meter, a single-phase circuit and its meter and a direct-current circuit and its meter. The totalizing equipment is connected to totalize on one register the load of these three circuits.

The watthour meters have contact devices operating from their registers. These devices make contact after a given quantity of energy have been registered on their respective meters. It is necessary that this quantity of energy have the same value for every meter belonging to the same totalizing unit. Each of these contact making devices is connected through an individual circuit to a relay which is located in the totalizing device.

The totalizing apparatus is equipped with a shaft continually rotated by an induction motor. On this shaft are located several discs, each of which is equipped with one tooth. The discs are so assembled that the teeth are located at equal intervals around the periphery when viewed along the shaft. For each disc there is a corresponding relay. The shaft and discs rotate freely as long as the relays are de-energized. As soon as one of the relays becomes momentarily energized, it attracts its armature and releases a lever. As the lever is released, it moves forward under spring action and pushes a pawl which engages into a tooth in a ratchet wheel and turns the wheel. This movement is transmitted, through suitable gearing, to the register. The tooth of the rotating disc, corresponding to the lever that has been released, then pushes the lever back to its original position where it is held by the armature of the relay, which, by this time, is again de-energized.

Each relay of the totalizing device controls an identical mechanism, and all ratchet wheels, which are actuated by the pawls, are connected with the register of the totalizing meter in such a manner that the excitation of each relay causes a definite advance of the register. If the excitation of the different relays is now so arranged that each of them is energized after a predetermined quantity of consumed energy has passed through its corresponding meter, then the register of the totalizing meter will give the correct sum of all the energy consumed in the different circuits.

The construction of the totalizing meter is such that the relays require a very small amount of energy for their excitation. Their current consumption is extremely small, therefore the distance between the different meters and the totalizing apparatus is of no importance. This device can be used for totalizing the registration of several meters located at some distance from each other.

The torque of the rotating shaft is sufficiently high to assure reliable performance of the totalizing device. The peripheral arrangement of the disc teeth as outlined above makes it impossible to lose the registration of a meter should any two contacts, located on two of the meters being totalized, function at the same instant.

The totalizing meter can be furnished with different types of demand attachments, such as a demand indicator or a chart for recording the demand (the maxigraph). In this way, a periodic demand reading may be obtained in addition to the totalized watthour registration of a number of circuits. This totalizing device can also be furnished with two or three gear ratios. Direct or alternating-current can be used to energize the relays, and it is not necessary that all relays be energized from the same source of potential, as the relay circuits are entirely independent of each other.

Thermal Converter Made by The Lincoln Meter Co., Ltd.

Thermo-couples are used in a device developed by the Lincoln Meter Company, Ltd., of Canada for totalizing the loads of several circuits. Fig. 28 and 29 show this instrument with the cover on and off respectively. Fig. 30 shows one of the thermal elements before the assembling of the current and potential windings.

Any number of loads may be totalized by associating a thermal element with each load. The various e.m.f's. generated by the thermo-couples are connected in series and are measured by a suitable d-c. millivoltmeter. A recording potentiometer, such as the Leeds and Northrup instrument, is preferable to a millivoltmeter, as it eliminates potential drops over the connecting leads. The distance over which such totalizing can be accomplished accurately depends upon the number of loads to be totalized and the loading of each thermal converter. Total distances up to ten miles have been covered satisfactorily, and loads have been measured up to 145,000 kw. It is claimed that maintenance has been reduced to a minimum due to the elimination of moving parts in the thermal elements installed at the various load points. This device has the added advantage in that its accuracy is not affected by changes in resistance of the interconnecting lines when the null method of measurement is employed (potentiometer).

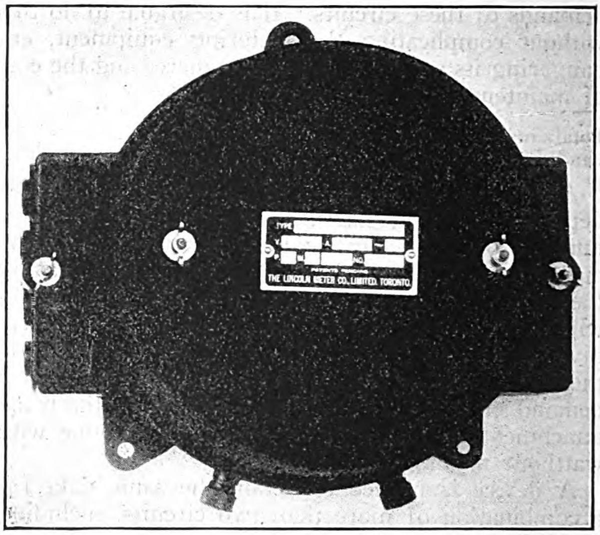

FIG. 28—THERMAL CONVERTER TYPE OF TOTALIZING METER MADE BY THE LINCOLN METER COMPANY, LTD.

Type RA Duplex Totalizing Watthour Demand Meter Made by The Westinghouse Electric & Manufacturing Co.

The meter shown in Fig. 31 is designed to totalize the watthour reading and the demand of two separate polyphase circuits. It consists of two Type RA meters having two or three elements, mounted in one case. The totalizing is accomplished by means of a differential register. A four-pointer dial shows the totalized reading while the totalized

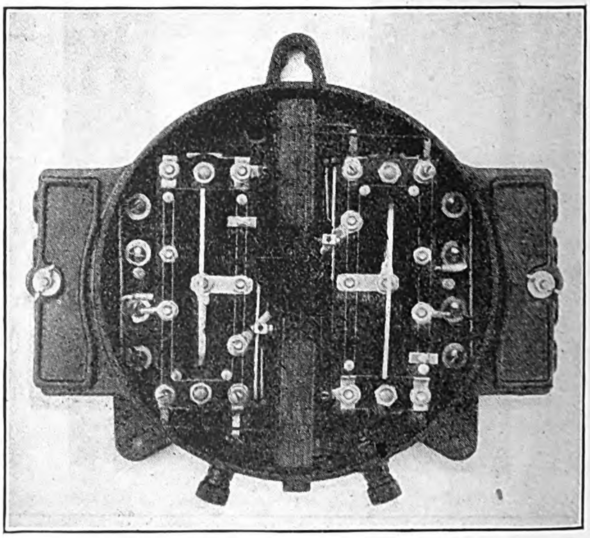

FIG. 29—LINCOLN TOTALIZING METER—COVER REMOVED.

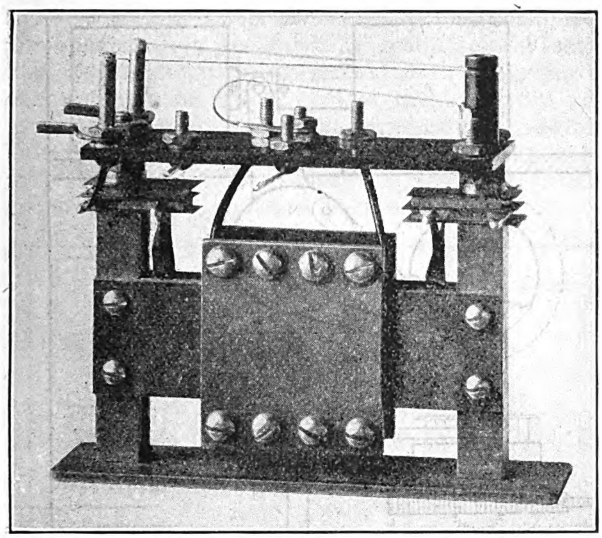

FIG. 30—THERMAL ELEMENT OF THE LINCOLN TOTALIZING METER—BEFORE ASSEMBLING THE CURRENT AND POTENTIAL WINDINGS.

demand is recorded on one RA chart. A second register is used to record the energy integrated on one of the circuits, thus making it possible to obtain the watthour reading of both circuits separately in addition to the totalized results. It is necessary to use instrument transformers of the same ratio on both elements or to compensate for the difference in the transformer ratios by special gearing in the register.

Type DT Totalizing Relay Made by The General Electric Co.

The Type DT Relay is designed to totalize the measurements obtained on a number of watthour meters and to transmit this total registration to a suitable recording device. The relay is made with two, four, six or eight elements.

The four-element relay shown in Fig. 32 has four sets of solenoids (A - B in Fig. 33) each of which may be operated from one of four watthour meters. The four sets of solenoids, when energized by impulses transmitted by the watthour meters, move crown wheels E, F, G and H (Fig. 33). This motion is transmitted to ring gears L and M and then to gears O and P. Gears O and P transmit their movement to crown wheels Q and R and finally to gear S, which is mounted loosely on contact shaft I. Gear S is connected to gear K, which is rigidly connected to shaft I by means of a spiral spring. As gear S advances, gear K becomes free to move and advances under the action of the spring until a pin attached to gear K rests against a pin attached to gear S. This motion is transmitted to contact cams T and the contacts transmit the impulses to the demand meter. In the four-element relay, one impulse is sent to the demand meter for every four impulses received from the watthour meters (one impulse from each of the four watthour meters, four impulses from any one of the watthour meters, or any other combination resulting in a total of four impulses).

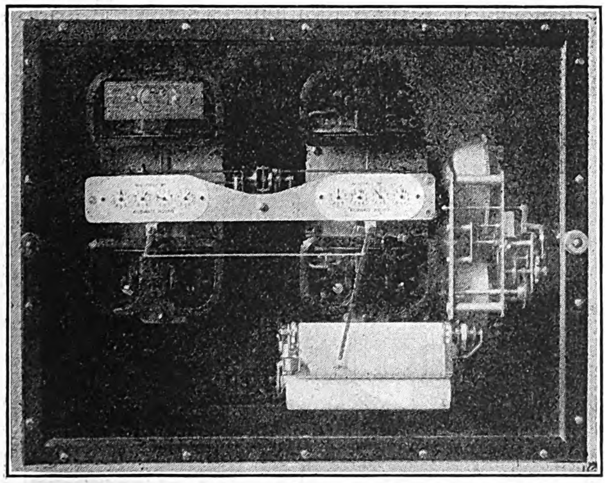

FIG. 31—TYPE RA DUPLEX TOTALIZING WATTHOUR DEMAND METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

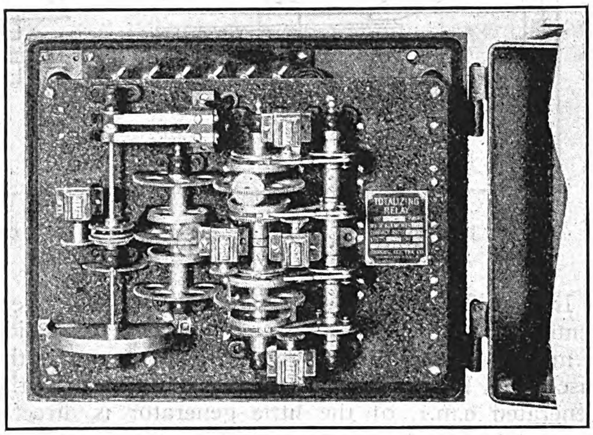

FIG. 32—TYPE DT TOTALIZING RELAY MADE BY THE GENERAL ELECTRIC COMPANY—FOUR-ELEMENT DEVICE.

Shaft N, carrying an aluminum disc running between the poles of a permanent magnet, is geared to shaft I and reduces its speed of rotation through the braking action of the disc, thus enabling the demand meter to record all impulses. With this arrangement, even if a very large number of impulses are received from the four watthour meters within a very short time, shaft I will turn under the action of the spiral spring, but will be sufficiently retarded by the drag magnet to permit the successive transmission of the impulses to the demand meter at the proper rate to insure correct recording.

Totalizing Equipment Made by The Aron Meter Works

The device described has been developed, primarily, to fill the demand for a reliable and simple means of totalizing the output of a number of generators or generating stations, irrespective of the distance between the units or stations. The essential parts of this equipment are the transmitter and the receiver.

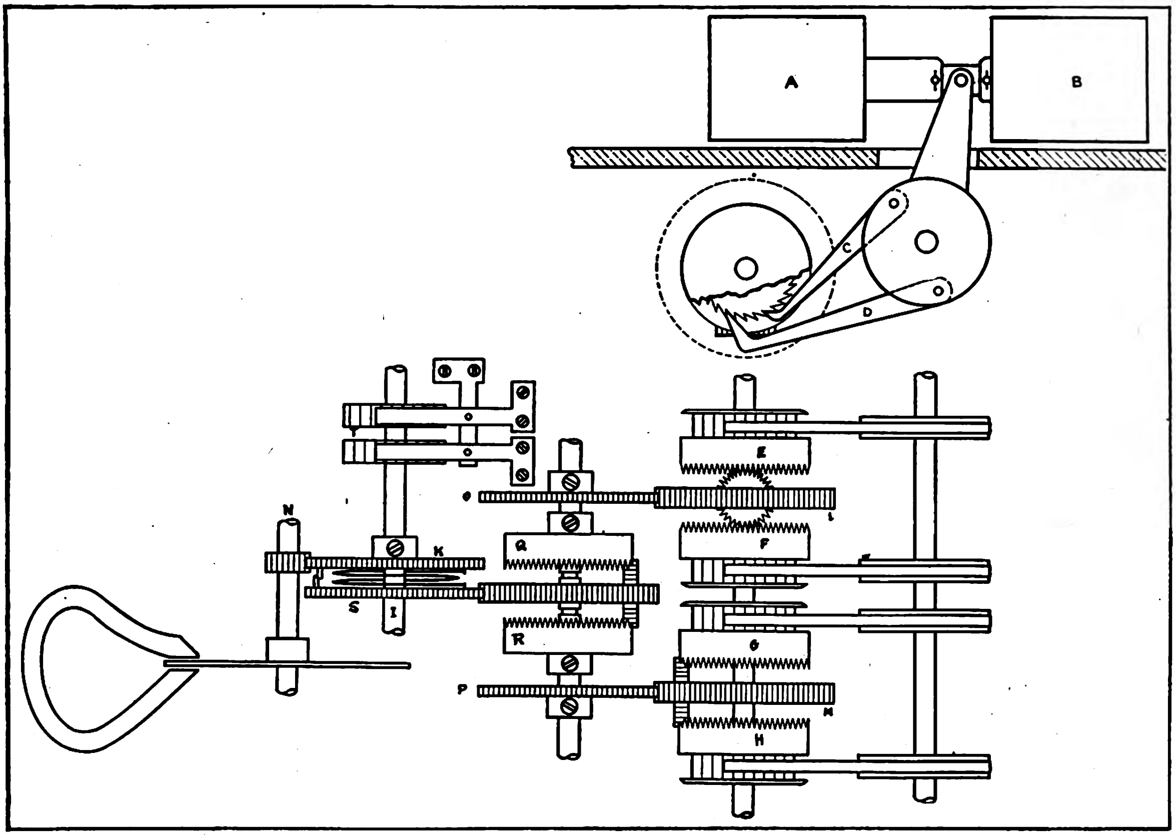

FIG. 33—SCHEMATIC DIAGRAM OF THE GEAR MECHANISM OF THE FOUR-ELEMENT TYPE DT TOTALIZING RELAY.

In Fig. 34 is shown the transmitter, which is essentially a watthour meter, on the shaft of which is mounted a small direct-current generator. As the disc speed is proportional to the power, and as the generated e.m.f. of the little generator is directly proportional to the disc speed, the e.m.f. generated is directly proportional to the power being measured. The receiver, therefore, is calibrated in kilowatts, or megawatts, and takes the form of a suitable millivoltmeter to indicate or to record graphically the e.m.f. of the transmitter. In Fig. 35 are shown four forms the receiver can take.

In Fig. 36 is shown the wiring diagram of the Aron Totalizing Equipment consisting of a transmitter, four indicating receivers, and one recording receiver. The indicating receiver located near the transmitter is intended to give the operator at the sending end an indication of what is being transmitted. The other four receivers are supposed to be installed in various locations to show the load to interested persons.

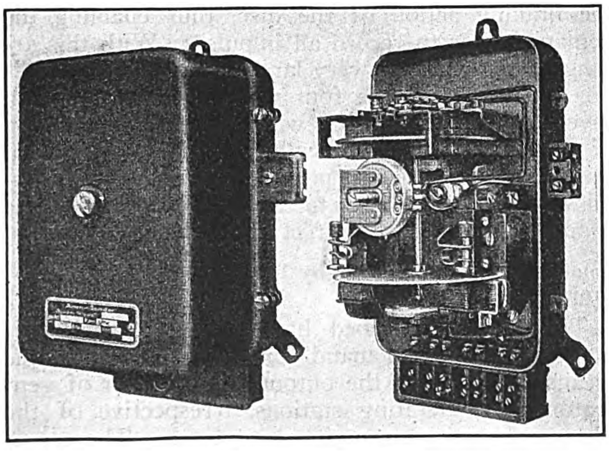

FIG. 34—TRANSMITTER OF TOTALIZING EQUIPMENT MADE BY THE ARON METER WORKS.

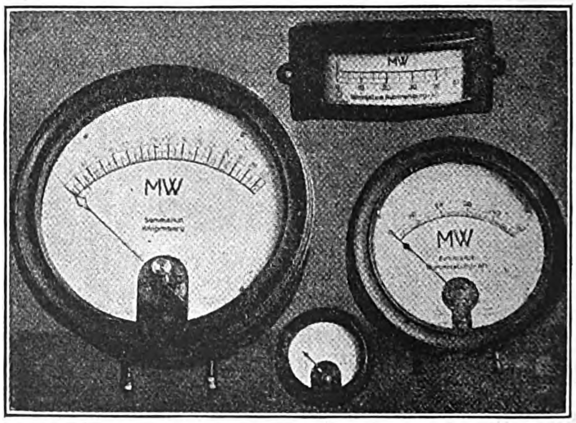

FIG. 35—RECEIVERS OF TOTALIZING EQUIPMENT MADE BY THE ARON METER WORKS.

For totalizing purposes a number of transmitters are connected in series. The manufacturer states that, as the quantity transmitted is of the order of one milliampere (d-c.) at less than 10 volts, the usual telephone or telegraph wires can be used and long distances may exist between the various transmitters. He also states that the telephone or telegraph wires used for this purpose can also be utilized for communication purposes without any interference between the two functions.

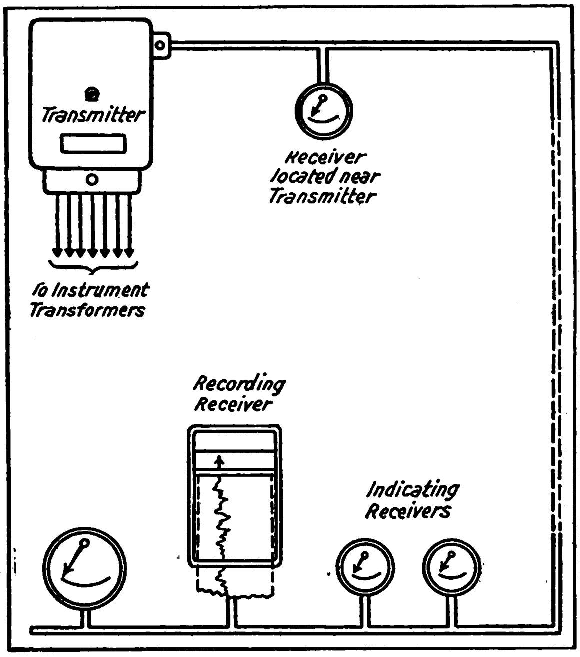

FIG. 36—Diagram of Connections of Totalizing Equipment Made by the Aron Meter Works.

The following advantages are claimed for this device by its manufacturer:

1. As the quantity transmitted and detected by the receiver is a direct-current, energy coming from sources which are not in synchronism can be totalized on one and the same receiver.
2. As the transmitter coils have impedances comparable to that of the usual type of watthour meter, the device can be connected to existing current and potential transformers without overburdening them.
3. The current to be transmitted being very small, wire of very small cross-section can be used. Furthermore, the resistance change with temperature of the transmitting wires can be rendered negligible by the use of a series resistor made of zero temperature coefficient wire. This is possible because the current to be transmitted is of the order of one milliampere. Such temperature compensation would be impossible if the currents to be measured were to be transmitted as obtained from the current transformers.
4. As the quantities to be measured are converted at the transmitter, no auxiliary equipment such as batteries or relays are required.
5. The accuracy of the system is of the order of that of the usual type of switchboard instruments.

Although a transmitter of the watthour meter type has been described, the manufacturer states that any of the usual electrical quantities such as amperes, volts, watts, volt-amperes, etc., can be taken care of by suitable design of the driving element of the transmitter. The small d-c. generator mounted on the shaft of the transmitter and the receiver are, of course, common to all applications. All that is necessary is to change the scale marking of the receiver to agree with units to be totalized or transmitted.

Instrument Transformers

The insistent demand of the industry for more accurate metering of electricity has not only promoted a marked improvement in watthour meter construction but has also resulted in a decided advance in the art of building instrument transformers. This applies chiefly to the current transformer.

The characteristic curves shown in this section have been submitted by the manufacturers of the several makes of transformers. No attempt has been made to verify them. A study of these curves indicates that a marked improvement has been accomplished in the light load performance of those transformers. Better performance is also obtained at heavier secondary burdens.

Types KF-85, and KF-58 Instrument Current Transformers Made by The General Electric Co.

The General Electric Co. announces two new types of instrument current transformers for indoor use. The Type KF-85 is designed for 7500-volt circuits and the Type KF-58 for 15,000-volt circuits. These will supersede the Types KC-85 and KC-58 respectively. The new transformers have improved ratio

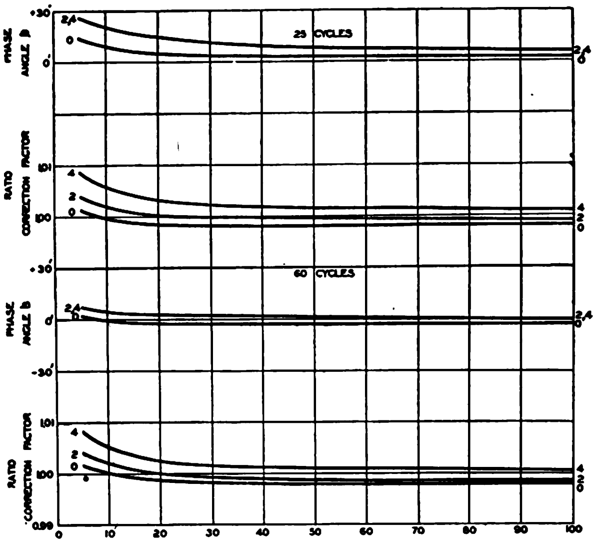

FIG. 37—Characteristic Curves of Type KF-85 and KF-58 Current Transformers Made by the General Electric Company.

and phase angle characteristics as shown by Fig. 37. In this figure, curves obtained at three different burdens are shown. The values of these burdens are given in the following table:

Burden No.	Volt-Amps.	Watts	Power Factor	Effective Ohms	Micro-henrys
0	6.0	6.0	1.00	0.240	......
2	19.2	17.05	0.89	0.682	936.0
4	45.1	24.28	0.54	0.971	4035.0

The mechanical features and appearance of these transformers are unchanged, as shown by Fig. 38 and 39.

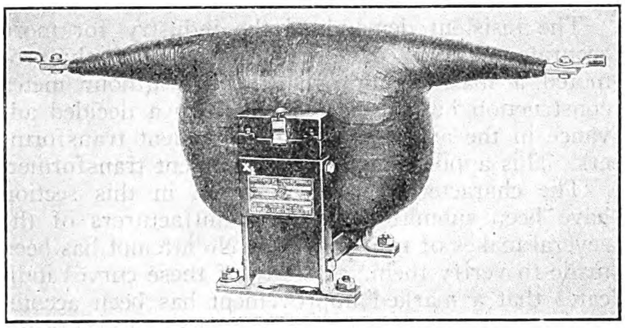

FIG. 38—TYPE KF-58 CURRENT TRANSFORMER MADE BY THE GENERAL ELECTRIC COMPANY.

In this new line of current transformers a very high degree of accuracy has been obtained by the use of certain corrective methods. Not only has the ratio error been minimized and the phase angle been reduced, but the slopes of the curves have been greatly reduced as well.

The principle upon which the ratio corrector operates is that of automatically changing the effective secondary turns as the load increases or decreases. For example, assume a ratio correction factor of 1.010 for 10 per cent load and of 1.000 for 100 per cent load. This indicates that at 10 per cent load the secondary current will be 1 per cent too small and at 100 per cent load it will be correct. Therefore, if we could remove 1 per cent of the secondary turns at 10 per cent load and gradually add them back as the load increased to 100 per cent, the curve would be flat and correct at all points from 10 per cent to 100 per cent load.

A special form of iron core has been designed. This, together with the ratio and phase angle corrector, is shown schematically in Fig. 40. Enough secondary turns are dropped to place the curves correctly. Then enough corrective turns are added, be-

FIG. 39—CONSTRUCTION DETAILS OF THE TYPE KF-58 CURRENT TRANSFORMER.

ing wound through the holes, passing transversely through the core to properly straighten out or flatten the curves. From the sketch it will be noted that holes, passing transversely through the core, divide the flux path into two sections, A and B, and A′ and B′. At lower values of primary current (low load), the flux will divide in a certain proportion between the paths A and B and A′ and B′. As the primary current increases, a greater proportion of the flux will pass through paths B and B′ because of a change in the relative permeability of these parts, thus causing the corrective turns to have less and less effect as the current increases. Therefore, at full rated primary current, the distribution of the flux in these sections of the core is such that the corrective turns have very little effect, while at lower primary currents, where the ratio curve would naturally begin to turn up, the flux distribution changes so that the corrective turns have an increasingly greater effect. Thus, by the proper selection of the number of corrective turns, and with the correct proportioning of the sections A and B and A′ and B′, the ratio curve can be flattened to practically a straight line.

The phase-angle corrector consists of a short-circuited turn of wire around section A or A′ or both. This corrector is similar in its action to that of the lag plate of an ordinary watthour meter. The action of the flux due to the current induced in this wire has the effect of lagging the main flux slightly. This lagging of the main flux throws the reversed secondary current nearer in phase with the primary current, thus reducing the phase angle of the current transformer. The magnitude of the effect of this phase-angle corrector varies in the same manner and for the same reason as the ratio corrector described above. As in the case of the ratio corrector, the effect is greater at light loads than at full loads, tending to straighten the phase-angle curve and to reduce the angle.

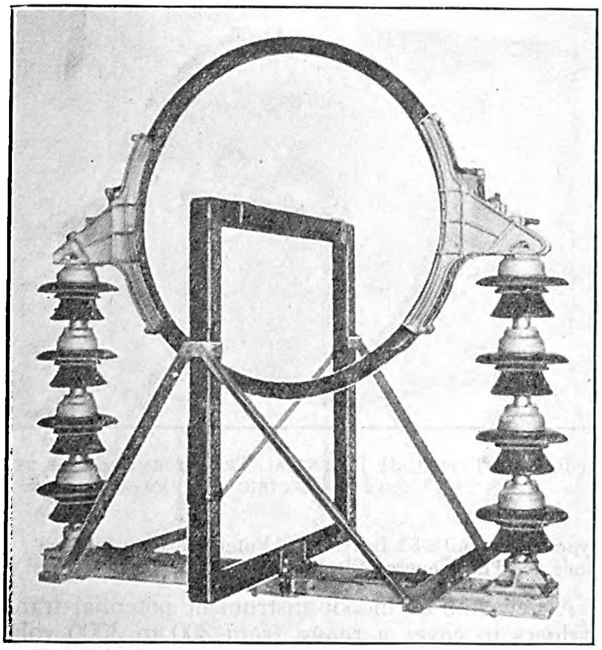

FIG. 41—AIR-INSULATED CURRENT TRANSFORMER MADE BY THE NIAGARA ELECTRIC IMPROVEMENT CORPORATION.

High-Voltage, Air-Insulated, Current Transformer Made by The Niagara Electric Improvement Corp.

The air-insulated current transformer has found its place in the development of high tension distribution systems. A high-voltage, air-insulated current transformer made by the Niagara Electric Improvement Corp. is shown in Fig. 41. The primary coil of this transformer is supported on conventional type high-tension insulators providing the necessary clearance between the primary and the core on which the secondary coil is wound.

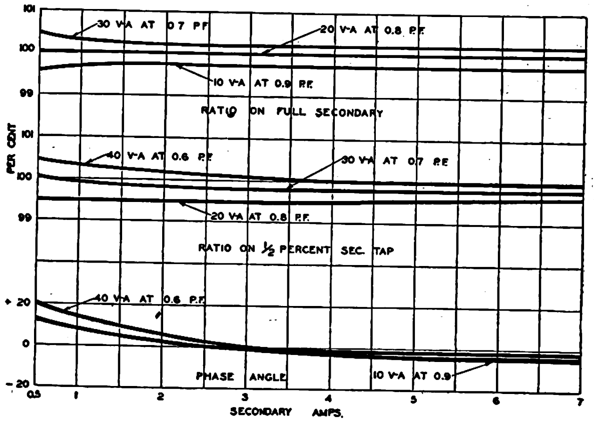

FIG. 42—CHARACTERISTIC CURVES OF AIR-INSULATED CURRENT TRANSFORMERS.

The manufacturer makes the following claims for these transformers:

1. Easy adaptability to outdoor bus and switch structures permits simplified current transformer installation.
2. Simplicity of design affords complete accessibility and visibility of parts.
3. Non-deteriorating air insulation between primary and secondary insures continuous and uninterrupted operation.
4. Windings will not be distorted under extreme overload and short circuit conditions.
5. Excellent accuracy resulting from a small ratio error and phase angle, which is desirable for all kinds of power measurements.

Fig. 42 shows the characteristic curves for this type of transformer as submitted by the manufacturer.

The manufacturer also claims that normal ratio is maintained up to ten times the rated current capacity, insuring dependable relay operation. The thermal capacity of windings is much in excess of that required by the A. I. E. E. specification. The guaranteed overload ratings are listed below:

80 times full load rated current for one (1) second.

55 times full load rated current for two (2) seconds.

45 times full load rated current for three (3) seconds.

40 times full load rated current for four (4) seconds.

35 times full load rated current for five (5) seconds.

Due to the open construction, the ratio can be varied by adding more turns to boost or buck the secondary current. The phase-angle also can be varied by short-circuiting loops placed at proper points.

Type NA Current Transformer Made by The Westinghouse Electric & Manufacturing Co.

The Westinghouse Electric & Manufacturing Co. placed on the market recently a current transformer in which the new "Hipernik" steel is used in place of the usual silicon steel. Hipernik steel was developed by Westinghouse research engineers who claim that it has three times the permeability of silicon steel with but half the losses. These characteristics are desirable for good transformer design. So far, this material has been used in the 7500-volt transformer only. The new current transformer is known as the Type NA, and is obtainable in all standard current capacities. The new design shows decided improved performance in respect to ratio and phase-angle as compared with the Type KA which it supersedes. Fig. 43 and 44 show the performance characteristics of the Type NA current transformer as submitted by the manufacturer.

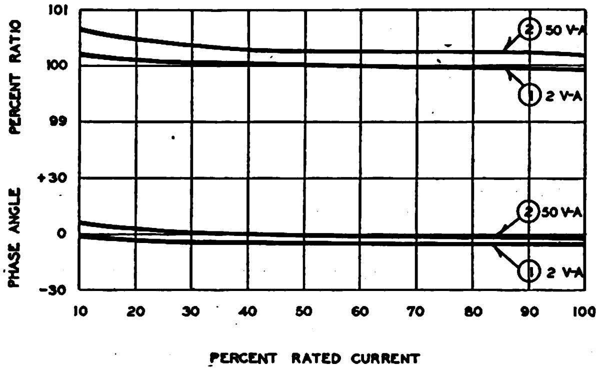

FIG. 43—Characteristic Curves of Type NA Current Transformers Made by the Westinghouse Electric & Manufacturing Co.—Effect of Secondary Burden Variation.

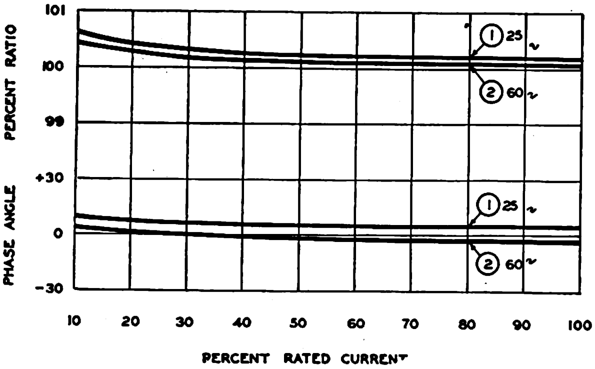

FIG. 44—Characteristic Curves of Type NA Current Transformer—Effect of Frequency Variation.

The mechanical improvements include a secondary terminal block provided with a sealable cover and equipped with an automatic short-circuiting device. The primary terminals are located along the center line of the windings and are equipped with two-bolt pressed-tube terminals. The inside bolt holes of the primary terminals have been placed 12½ inches apart on transformers of all capacities, making them interchangeable with each other and with the Type KA units. The two sets of bolt holes also assist interchangeability with other types of current transformers.

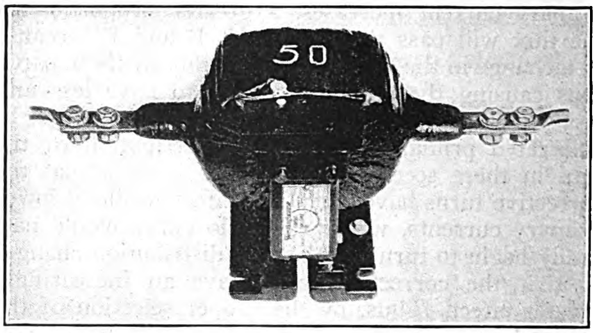

FIG. 45—Type NA Current Transformer Made by the Westinghouse Electric & Mfg. Co.

The mounting feet are designed for flat surface or transverse pipe framework mounting. The 50-ampere size transformer is shown in Fig. 45.

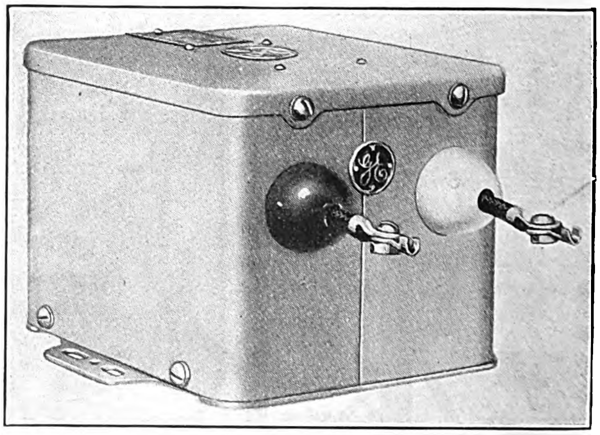

FIG. 46—Type E-31 Potential Transformer Made by the General Electric Company.

Types E-31 and E-32 Instrument Potential Transformers Made by The General Electric Co.

A new line of indoor instrument potential transformers to cover a range from 200 to 3000 volts, 60 cycles, has been developed by the General Electric Company. Transformers not provided with

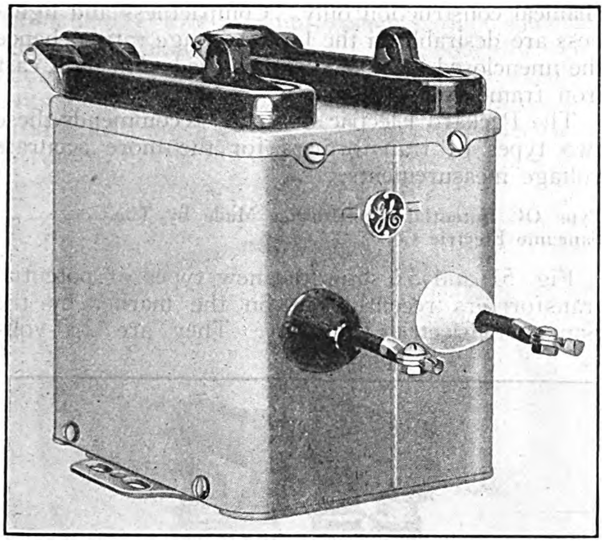

FIG. 47—TYPE E-32 POTENTIAL TRANSFORMER MADE BY THE GENERAL ELECTRIC COMPANY.

fuses are designated Type E-31, Fig. 46, and those provided with fuses are designated Type E-32, Fig. 47. They are rated 100 volt-amperes under the General Electric standard of rating instrument transformers, and are compensated for 50 volt-amperes at 115 volts secondary. The thermal rating (maximum allowable burden) is 300 volt-amperes.

The windings of these transformers are heavily insulated. Varnished cambric is used between end layers. The insulation of the primary conductors and sections of the primary coil is such as to produce unusually high factors of safety.

The core and windings are enclosed in a heavy metal casing. The secondary leads are brought out through a metal connection box of standard design which can be mounted in any one of the four quadrant positions by simply changing the position of two screws. This facilitates the installation of the conduit wiring. If this is not desired, the connection box can be readily removed. The primary bushings are made of a single piece of porcelain, and are fastened to the casing by a steel clamping ring.

These transformers have subtractive polarity. The primary polarity markings are made permanent by the use of white, and brown bushings, and one secondary lead is painted white. In addition polarity markings are embossed on the metal casing near the primary bushing and on the metal connection box near the secondary lead.

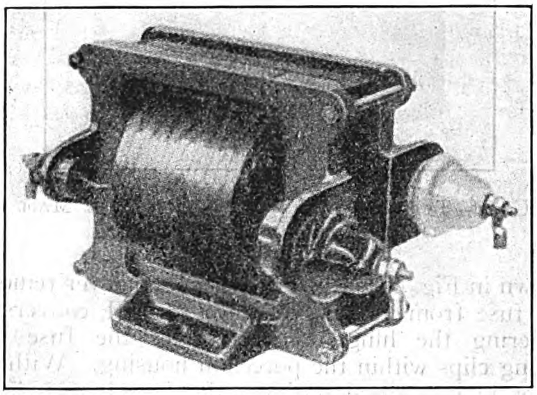

FIG. 49—TYPE PS POTENTIAL TRANSFORMER MADE BY THE PACKARD ELECTRIC COMPANY.

The Type E-32 transformer has fuse supports and housings of special design which facilitate inspection and renewal. This type of transformer with its special hinged cover fuse equipment is

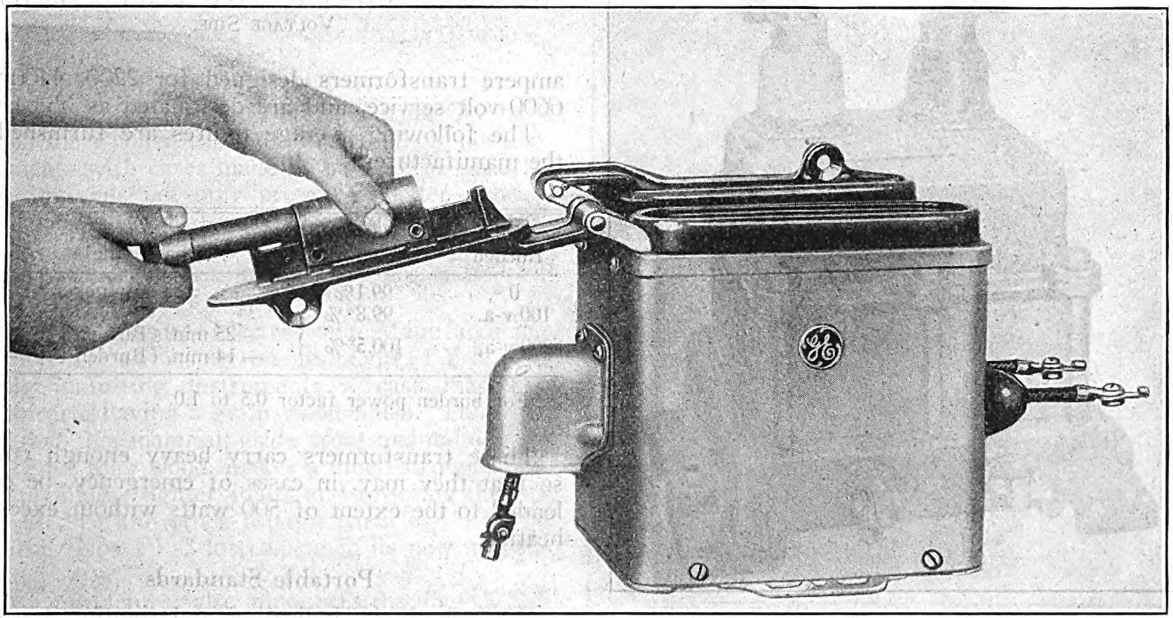

FIG. 48—TYPE E-43 POTENTIAL TRANSFORMER—METHOD OF REMOVING FUSE FROM FUSE HOLDER.

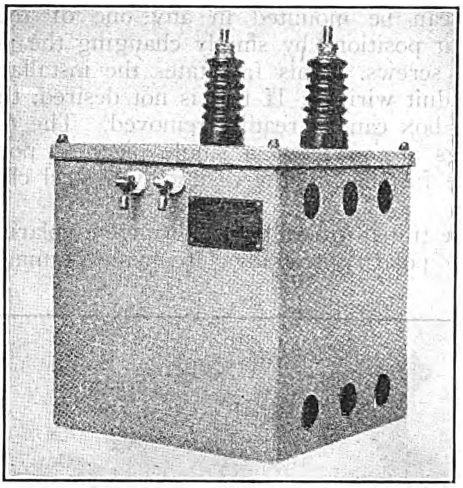

FIG. 50—Type PD Potential Transformer Made by the Packard Electric Company.

shown in Fig. 48. Raising the hinged cover removes the fuse from its clips in the block and, conversely, lowering the hinged cover forces the fuse into spring clips within the porcelain housing. With the cover in its normal position, the fuse is completely enclosed.

Types PS and PD Potential Transformers Made by The Packard Electric Co.

This company has developed two new lines of indoor dry type potential transformers. The Type PS, Fig. 49, is designed for use on the several standard primary voltages up to and including 6900 volts. The Type PD, Fig. 50, is available for 11,500 and 13,800-volt service.

The difference between these two types is in mechanical construction only. Compactness and lightness are desirable in the lower voltage rating, hence the unenclosed Type PS is furnished with light cast iron frame and feet.

The Packard Electric Company recommends these two types of transformers for the more accurate voltage measurements.

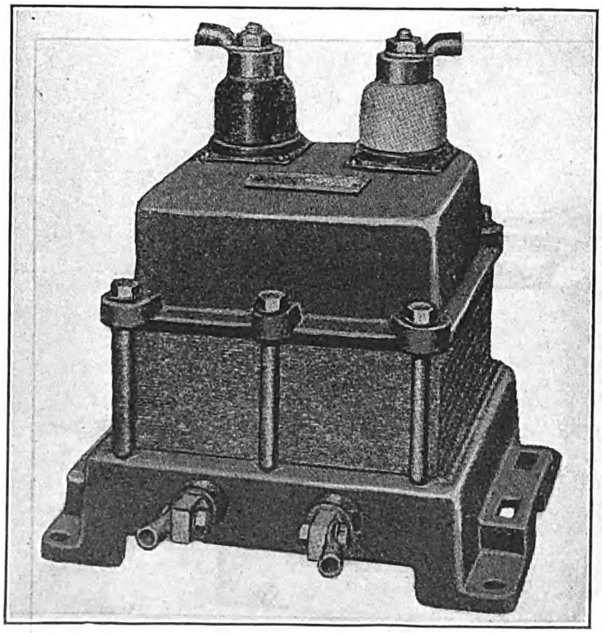

FIG. 51—Type OC Potential Transformer Made by the Sangamo Electric Company—Not Fused.

Type OC Potential Transformer Made by The Sangamo Electric Co.

Fig. 51 and 52 show the new types of potential transformers recently put on the market by the Sangamo Electric Company. They are 200-volt-ampere transformers designed for 2200, 4400 and 6600-volt service, and are designated as Type OC.

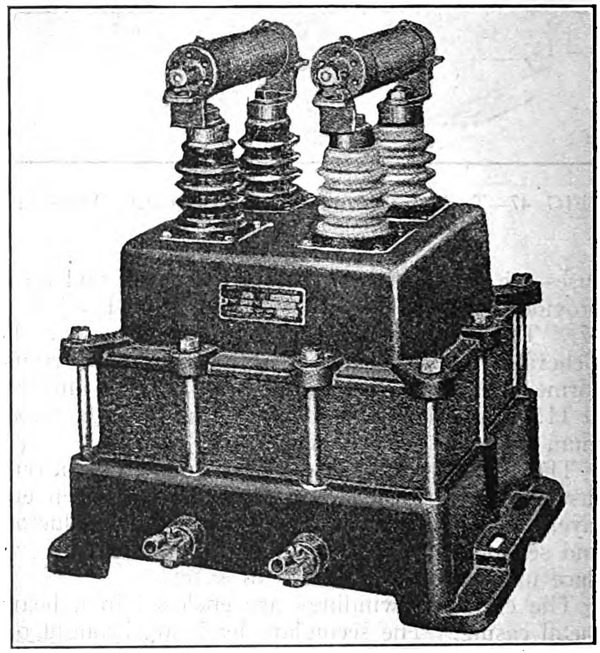

FIG. 52—Type OC Potential Transformer Made by the Sangamo Electric Company—Fused on the High Voltage Side.

The following average figures are furnished by the manufacturer:

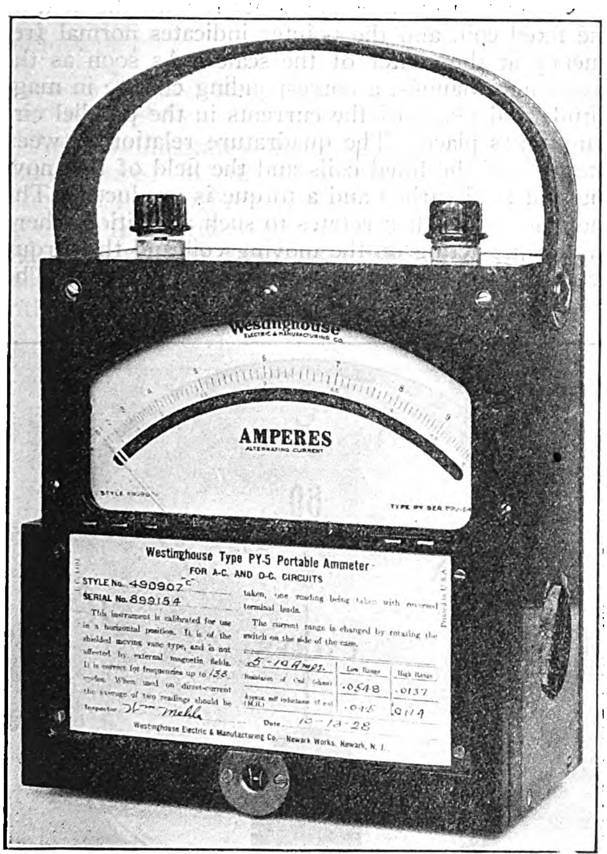
Secondary Burden	Ratio Factor	Phase Angle
0	99.1%	+ 3 minutes
100 v-a.	99.8*%	—
200 v-a.	100.5*%	— 25 min. (Burden P.F. = 1.0) — 14 min. (Burden P.F. = 0.5)

*For burden power factor 0.5 to 1.0.

These transformers carry heavy enough copper so that they may, in cases of emergency, be overloaded to the extent of 500 watts without excessive heating.

Portable Standards

While both the indicating and rotating types of portable standards have received their share of attention in the way of improvements, their general appearance remains the same. Consequently few announcements have been received of new developments in this line. A number of manufacturers of portable instruments, such as the Weston Electrical Instrument Corp., the General Electric Co., and the Westinghouse Electric and Manufacturing Co., have replaced the wooden cases of some of their portable instruments with cases made of bakelite or micarta. These materials not only present a better appearance than wood, but also are more durable.



Westinghouse
AMPERES
Westinghouse Type PY-5 Portable Ammeter
FOR A-C. AND D-C. CIRCUITS

FIG. 53—TYPE PY-5 AMMETER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.—MOUNTED IN MICARTA CASE.

Portable Instruments Made by The Westinghouse Electric & Manufacturing Co.

The Westinghouse Electric and Manufacturing Company is now using on its Type PY-5, a-c. portable indicating instruments a case made of sheet micarta having a grain wood finish. This firm claims that this material, aside from maintaining its finish better than wood, makes a much stronger box which maintains tighter joints and prevents the entrance of dust and other foreign particles. Fig. 53 shows the Type PY-5 instrument in its new micarta case.

This manufacturer also announces the Type PX-5 line of portable direct-current instruments furnished in a case similar to that of the PY-5.

Type OB Portable Watthour Meter Made by The Westinghouse Electric & Manufacturing Co.

The Type OB portable watthour meters are now available in either two or five current ranges. The five current range meter is wound for 1, 5, 10, 25 and 50 amperes. The case is of one-piece micarta with mahogany finish, Fig. 54. The meter weighs eight pounds, and its dimensions, less handle, are 4¾ in. by 6½ in. by 6½ in.

Frequency Meters, Indicating and Graphic

Modern practice in station operation, incident to the development of large electrical systems involving the interconnection of large capacity units, have created a demand for more accurate frequency

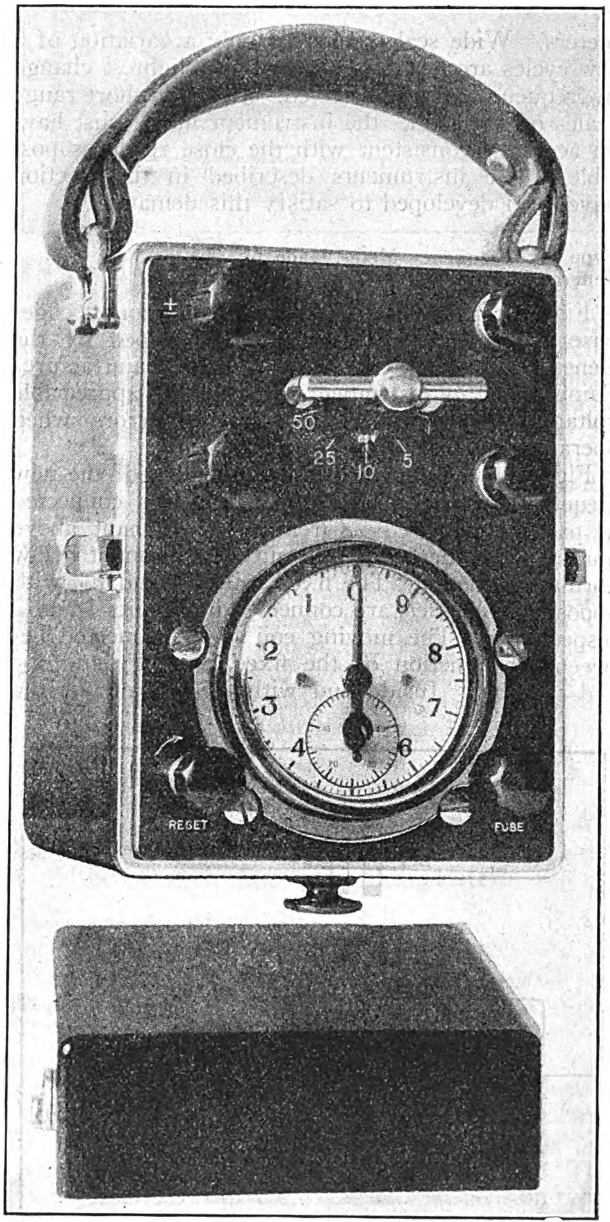


FIG. 54—TYPE OB PORTABLE WATTHOUR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

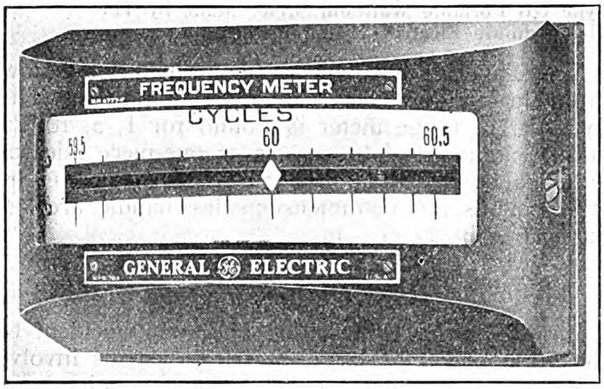

FIG. 55—Type H-8 Frequency Meter Made by the General Electric Company.

meters. Wide scales covering only a variation of a few cycles are desirable, so that the slightest change in frequency may be detected. To make short range scales of any value, the instrument itself must have an accuracy consistent with the close readings possible. The instruments described in this section have been developed to satisfy this demand.

Type H-8 Frequency Meter Made by The General Electric Co.

Fig. 55 shows the Type H-8, a horizontal edgewise frequency meter, recently developed by the General Electric Company. The manufacturer claims that this instrument is free from appreciable voltage, wave-form, or temperature errors when operating under extreme conditions.

Fig. 56 shows the circuit arrangement of the new freqency meter. Two resonant circuits connected in parallel are used. Circuit 1 is resonant above normal frequency, while circuit 2 is resonant below normal frequency. The fixed coils, F_1 and F_2, with opposing polarities, are connected in circuits 1 and 2 respectively. The moving coil M is connected between the junction of the fixed coils, F_1 and F_2, and the line. Inside and within the plane of the moving coil is an iron vane. The resistance of circuit 1 is approximately equal to that of circuit 2, therefore, the currents in the two parallel circuits are equal at normal frequency.

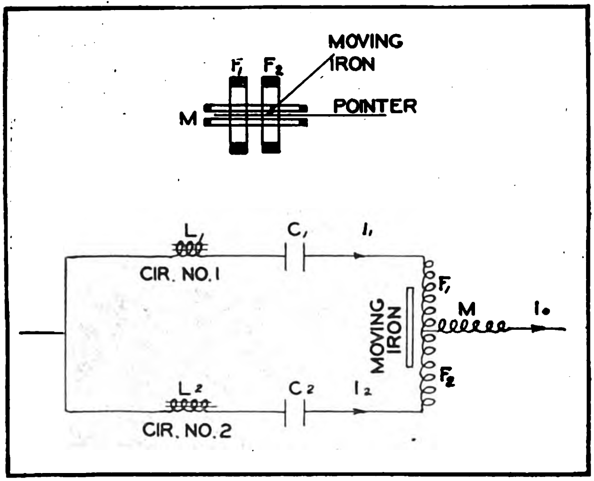

FIG. 56—Schematic Diagram Showing the Internal Connections of the Type H-8 Frequency Meter.

At normal frequency the field of the fixed coils is in quadrature with the field of the moving coil. Therefore, no torque is exerted on the moving coil. The moving iron vane aligns itself with the field of the fixed coil, and the pointer indicates normal frequency at the center of the scale. As soon as the frequency changes, a corresponding change in magnitude and phase of the currents in the parallel circuits takes place. The quadrature relation between the field of the fixed coils and the field of the moving coil is disturbed and a torque is produced. The moving system then rotates to such a position where the torque acting on the moving coil and the torque acting on the iron vane are equal and opposite. The deflecting torque is proportional to the difference of the squares of the currents in the two parallel circuits. Due to this fact, the instrument is referred to as a "differential" frequency meter. The restoring torque (control torque) is proportional to the square of the resultant current.

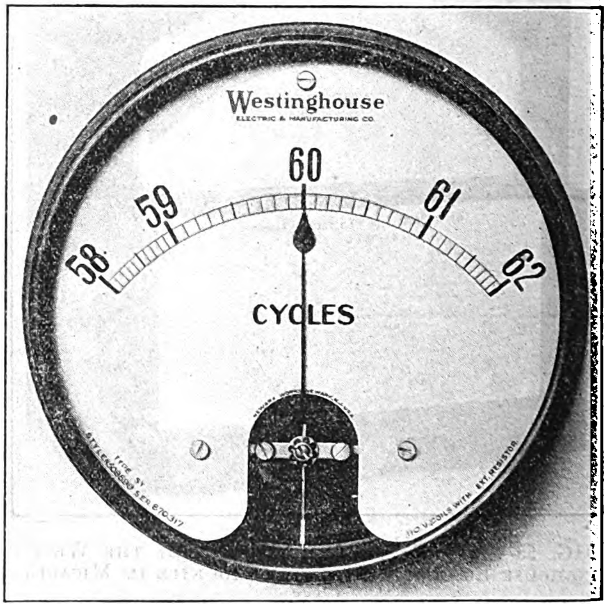

FIG. 57—Type SY Frequency Meter Made by the Westinghouse Electric & Mfg. Co.

The normal position of the pointer, at the center of the scale, is fixed by the position of the iron vane on the moving coil shaft. The scale characteristic is determined by the angle between the iron vane and the shaft.

The Type H-8 instruments are supplied with an external resistor for use on 110-volt circuits. For higher voltages, potential transformers are necessary. The following scale ranges are available: 59.5 to 60.5 cycles; 59 to 61 cycles; 55 to 65 cycles; 45 to 55 cycles; and 22.5 to 27.5 cycles.

Type SY Indicating Frequency Meter Made by The Westinghouse Electric & Manufacturing Co.

The Westinghouse Electric and Manufacturing Company has now on the market the Type SY frequency meter for use on switchboards. This is a short-range scale instrument of the resonant type, Fig. 57. The manufacturer advises that it has a torque equal to that of switchboard ammeters and voltmeters.

Frequency Recorder Made by The Esterline-Angus Co.

Fig. 58 illustrates the new frequency recorder manufactured by the Esterline-Angus Company. Single instruments are available in any of five types of cases for portable use and for wall or switchboard mounting. Twin cases are furnished in the wall or switchboard type mountings for combination with another frequency recorder or meter elements of other types. The weight of a single instrument is about 25 lb., and that of the twin type about 45 lb. The electrodynamic principle is employed. The scale of this instrument is 55 to 65 cycles and is distributed practically uniformly across a chart 4½ in. wide. The scale and record chart have ten main divisions, one for each cycle. Each main division is divided into four smaller divisions of ¼-cycle each.

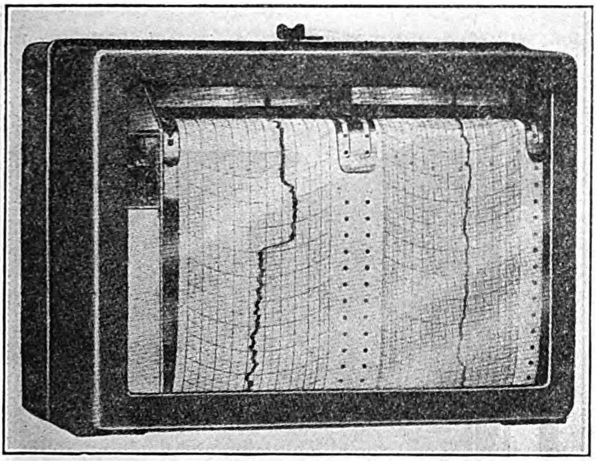

FIG. 58—FREQUENCY RECORDER MADE BY THE ESTERLINE-ANGUS COMPANY—MOUNTED IN A TWIN CASE WITH ANOTHER INSTRUMENT OF THE SAME MANUFACTURER.

This instrument can be furnished with spring-wound clocks for driving the chart at either ¾, 1½, 3, 6 or 12 in. per hour.

Type R Graphic Frequency Recorder Made by The Westinghouse Electric & Manufacturing Co.

The Westinghouse Electric and Manufacturing Company has on the market a recording frequency meter of the short-range type, Fig. 59. To measure frequency, this instrument uses the centrifugal force developed by a flyball governor driven by a synchronous motor. Any variation of the frequency produces a change in centrifugal force proportional to the difference of the square of the frequencies before and after the change. The force developed is transmitted through a mechanical linkage to a pivoted beam. Electrical contacts are located at the free end of this beam and a balance weight, linked to the pen carriage, rides on top of it. As the centrifugal force varies, the closing of one or the other of the electrical contacts causes a control motor to move the balancing weight and pen, maintaining a balance of force and weight and graphically recording the frequency variations.

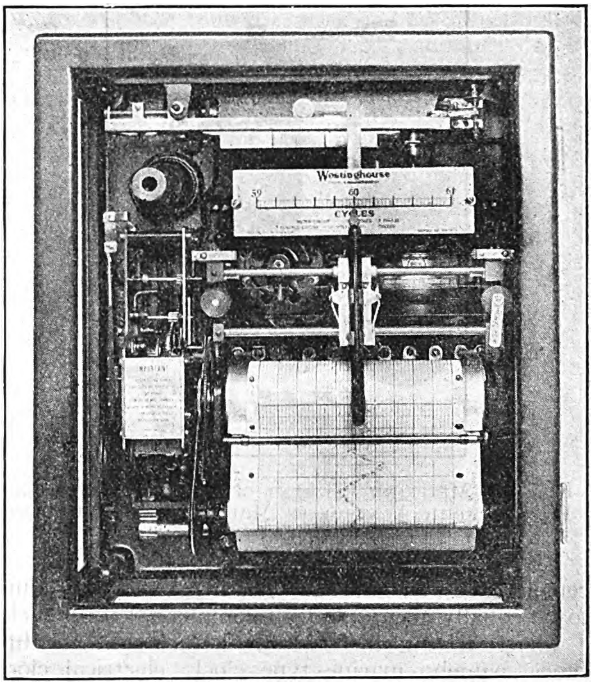

FIG. 59—TYPE R FREQUENCY RECORDER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

The manufacturer claims that this instrument is very accurate, sensitive, and rugged. The instrument illustrated has a scale of 59 to 61 cycles and a 5¼ in. chart traveling at the rate of 4 in. per hour.

Other Graphic Instruments

While the changes in the general line of graphic instruments has not been of a radical nature, they should be of some interest to the industry.

Three-Phase, Four-Wire, Graphic Wattmeter Made by The Esterline-Angus Co.

The Esterline-Angus Company is prepared to meet the increasing demand for a graphic wattmeter for use on three-phase, four-wire circuits. The metering element is of the electrodynamic type, having three stationary current coils and two potential coils as shown in Fig. 60. The current coils have a normal rating of 5 amperes but will carry 35 per cent overload continuously without overheating. The moving element is of the usual wire suspension type. The potential circuit is furnished with external resistors for use on 115, 230 or 575 volts, and is designed to operate satisfactorily on voltages 35 per

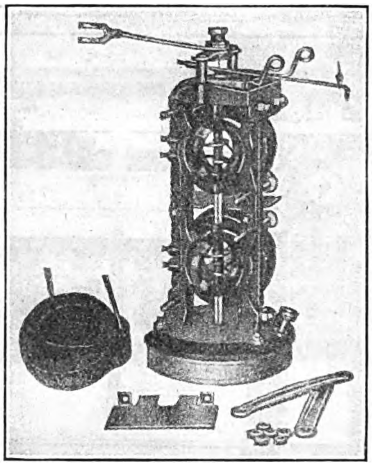

FIG. 60—METERING ELEMENT OF THREE-PHASE, FOUR-WIRE GRAPHIC WATTMETER MADE BY THE ESTERLINE-ANGUS COMPANY.

cent in excess of normal. The instrument is claimed to be equally accurate at all commercial frequencies.

Chart driving mechanism is furnished in three types, namely, marine type clock, electrical clocks suitable for use with impulse timing systems, and synchronous motor drive. Chart speeds of ¾, 1½, 3, 6 or 12 in. per hour are available. The instrument can also be furnished with a relay which can change the chart speed instantaneously from in. per hour to in. per second.

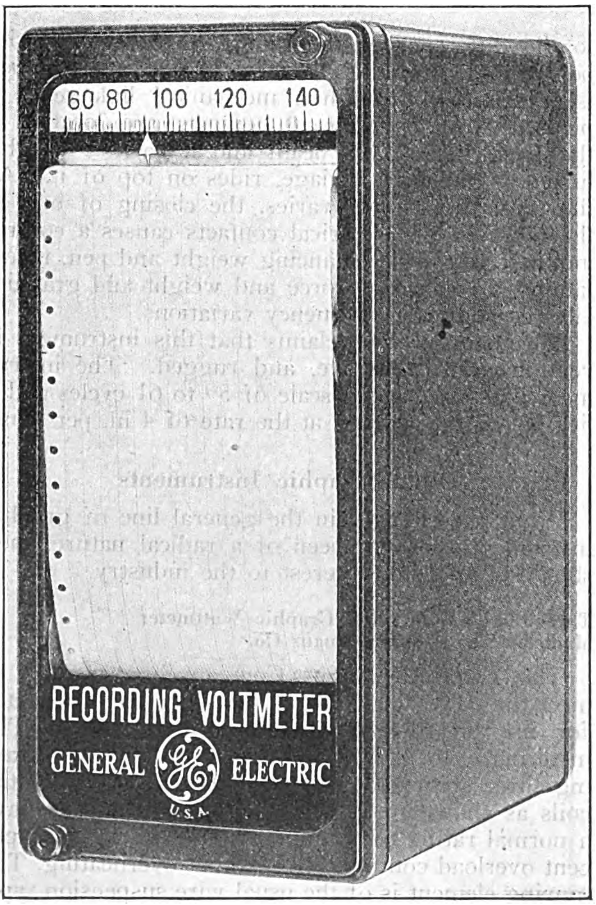

FIG. 61—TYPE CD STRIP CHART RECORDING VOLTMETER MADE BY THE GENERAL ELECTRIC COMPANY—SWITCHBOARD TYPE.

Three-phase, four-wire wattmeters are furnished in single portable, wall, and switchboard type cases. The twin type case is available for wall and switchboard mounting, for combining with any other graphic type instrument, except the volt-ampere meter.

Types CD and CDP Strip-Chart Recording Instruments Made by The General Electric Co.

The General Electric Company has placed on the market a complete line of general-purpose recording instruments for alternating-current and direct-current service, known as the Types CD and CDP. The metering element in the alternating-current instrument is of the electrodynamic type, while the direct-current element is of the permanent magnet type. The moving element of each is mounted in jewel bearings and damped magnetically.

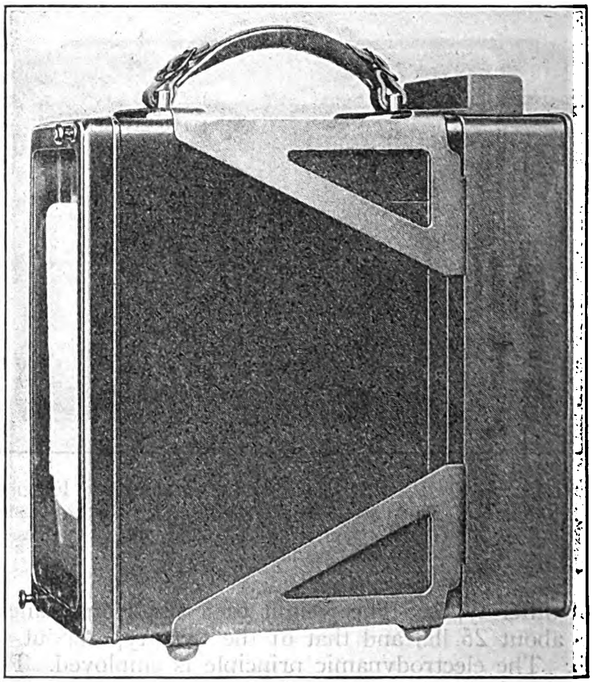

FIG. 62—TYPE CD STRIP CHART RECORDING INSTRUMENT MADE BY THE GENERAL ELECTRIC COMPANY—PORTABLE TYPE.

The record roll is 4⅜ in. wide and has a 4 in. scale. The standard chart speed is 3 in. per hour, but speeds of 1 in. or 2 in. per hour may be supplied with a spring wound clock mechanism. When a Warren synchronous motor clock is used, chart speeds of 1, 2, 6 and 12 in. per hour are available. These instruments are furnished for switchboard mounting as shown in Fig. 61, or for portable use as shown in Fig. 62. Fig. 63 shows

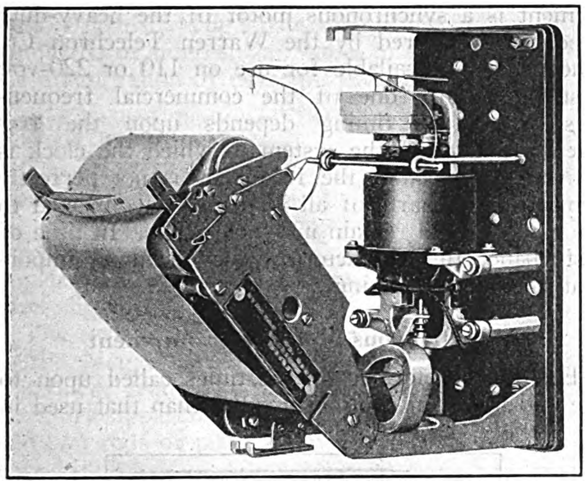

FIG. 63—INTERIOR VIEW OF A TYPE CD A-C. INSTRUMENT.

an internal view of the alternating-current instruments.

Type A Circular Chart Graphic Ammeters and Voltmeters Made by the Westinghouse Electric & Manufacturing Co.

The Westinghouse Electric & Manufacturing Co. has on the market a circular chart, Type A, graphic instrument available either as a voltmeter or an ammeter, Fig. 64. It operates on the electromagnetic principle, and the record is obtained with a pencil, rather than with ink in the usual manner. The manufacturer states that it is ruggedly constructed and has exceptionally strong torque.

Type R Power Factor Recorder Made by the Westinghouse Electric & Manufacturing Co.

There has been considerable discussion during recent years concerning the measuring and recording of three-phase power factor. The Westinghouse Electric & Manufacturing Co. announces a new Type R graphic power factor recorder (Fig. 65), which employs the principle of measuring the vectorial power factor of a three-phase system as recommended by the American Institute of Electrical Engineers.

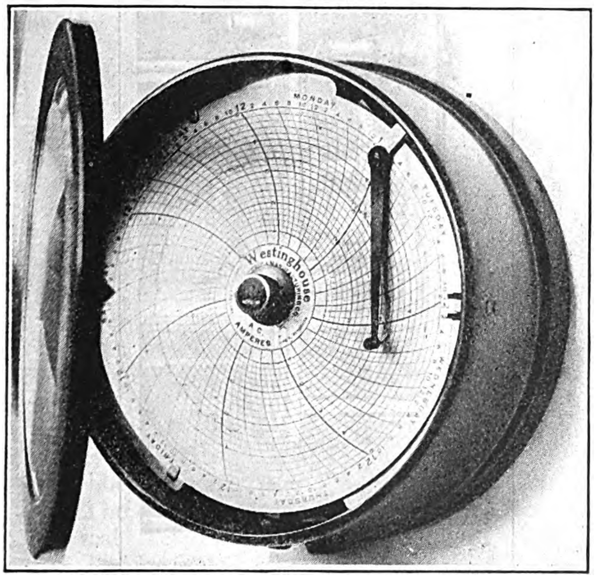

FIG. 64—TYPE A CIRCULAR CHART GRAPHIC INSTRUMENT MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

The manufacturer claims that this instrument will measure accurately the power factor when the current through the 5-ampere coils is as low as one ampere, within the frequency limits of 58 to 62 cycles. This instrument is also built for other frequencies, such as 25 and 50 cycles.

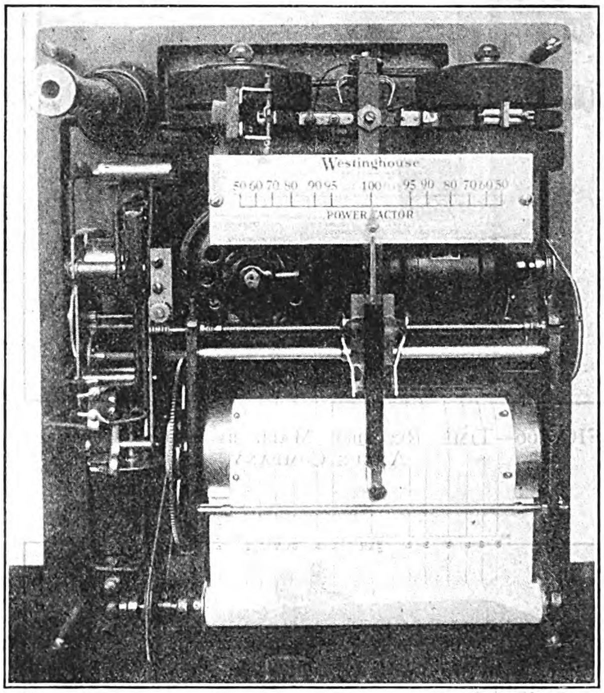

FIG. 65—TYPE R GRAPHIC POWER FACTOR METER MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

Time Recorder Made by the Esterline-Angus Co.

The Esterline-Angus Co. has developed a device for recording time. It consists of a graphic meter built along the general lines of their product. The timing elements consist of small relays which actuate separate pens. There may be 5, 10 or 20 of these, depending upon the model of instrument. Each relay may be used to time a separate operation, or may be used to show one operation in a complex cycle. They are excited from a source controlled by the operation being timed. The general design of this instrument is shown in Fig. 66 and 67.

Synchronous Clock Chart Drive Made by the Esterline-Angus Co.

Synchronous motor drive in use for some years on General Electric Co. recording instruments is now also available for Esterline-Angus graphic instruments. This device, Fig. 68, was developed to meet the demand for more accurate timing. The driving

connection with the measurement of customer, or station loads. The instruments discussed below should be of interest and value to those engaged in the investigation of electrical problems.

Megger Ground Resistance Tester Imported by James G. Biddle

The Megger Ground Resistance Tester is a direct-reading electrical instrument designed for measuring the resistance of ground connections such as driven pipes and rods, buried plates, patented grounding devices, water pipes, ground wires, steel structures, lightning arrester, etc.

The instrument is similar in size and appearance to the Megger Insulation Testing Set. It is self-contained, requiring no external current supply or auxiliary apparatus whatever, except flexible leads and two rods or pipes for use as auxiliary or reference grounds.

A number of ranges are available, from 0 to 3 ohms, up to 0 to 3000 ohms full scale, with as many as three ranges in the same instrument. Fig. 69 and 70 show a side and top view of the device. The following are some of the outstanding characteristics of the Megger Ground Resistance Tester as outlined by the manufacturer:

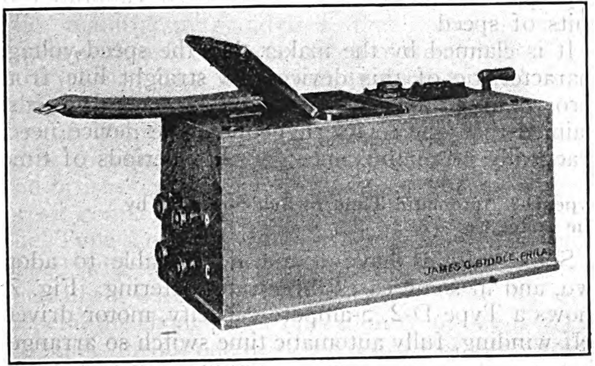

FIG. 69—MEGGER GROUND RESISTANCE TESTER IMPORTED BY JAMES G. BIDDLE.

1. It is direct reading, being of the pointer type, like a voltmeter, and requires no manipulation.
2. It is simple to use, requiring only the making of external connections, turning of the crank and reading.
3. It is portable and weighs only 21 lb.
4. Ground resistance in the vicinity of severe stray earth currents can be measured. Satisfactory results have been obtained with as much as 50 volts difference of potential between grounded points.
5. Variable resistance grounds can be determined because the instrument is direct reading, and the pointer follows instantaneously any change of resistance.
6. It is available in a wide assortment of ranges.
7. The method used permits of high accuracy.
8. The instrument is of the same rugged mechanical construction as the Megger Insulation Testing Sets.

The internal connections of the Megger Ground Resistance Tester are shown in Fig. 71.

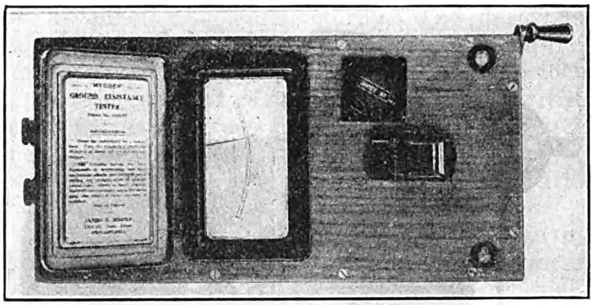

FIG. 70—MEGGER GROUND RESISTANCE TESTER—TOP VIEW.

Power Osiso Made by the Westinghouse Electric & Manufacturing Co.

The Westinghouse Electric & Manufacturing Co. has on the market a four-element power Osiso, Fig. 72 and 73. Although it can be used in the laboratory for general oscillograph work, it has certain special features which make it particularly desirable for investigation of line disturbances. For study of disturbances the Osiso can be made to start in 0.03 second after the disturbance starts. The normal film speed is 3 in. per second, but it can be decreased automatically, if desired, to ½ in. per second after the disturbance has somewhat subsided. The film holder is of the daylight loading type and accommodates a 5 ft. or 10 ft. film. A dark-room film holder that can accommodate a 15 ft. film is also available.

Single-Phase Klydonograph Made by the Westinghouse Electric & Manufacturing Co.

A single-electrode or single-phase Klydonograph has recently been placed on the market by the Westinghouse Electric & Manufacturing Co. This instrument is similar to the three-phase Klydonograph but has only one electrode, and makes use of a film pack instead of roll film. The index pointer

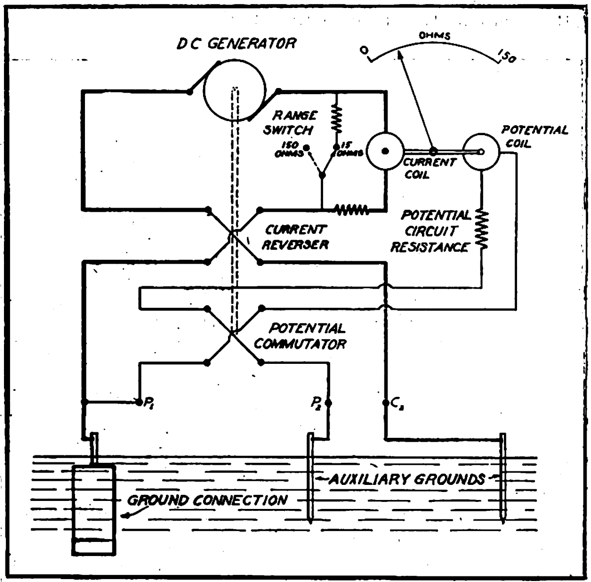

FIG. 71—CONNECTION DIAGRAM OF THE MEGGER GROUND RESISTANCE TESTER.

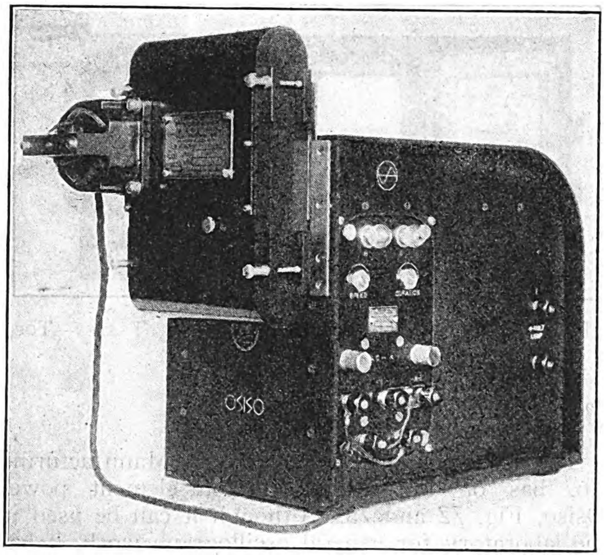

FIG. 72—POWER OSISO MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.—MOTOR AND SHUTTER CONTROL PANEL.

on the bottom of the instrument can be advanced one position each day, which moves the electrode to a different position on the film. Therefore, one film may serve to obtain records for one week. The Lichtenberg figures produced on the film have the same characteristics as those produced on the roll film of the larger size, four-electrode, Klydonograph.

The instrument may be connected to the circuit in a manner similar to an electrostatic potentiometer, *i.e.*, taking the potential drop along a string of suspension insulators, to obtain approximately 1800 volts.

The instrument is mounted in a horizontal position and can be installed on the cross arm of a pole or a specially constructed framework. Fig. 74 shows the top view of the single-phase Klydonograph with cover on, while Fig. 75 shows a bottom view. Both figures show the mounting studs.

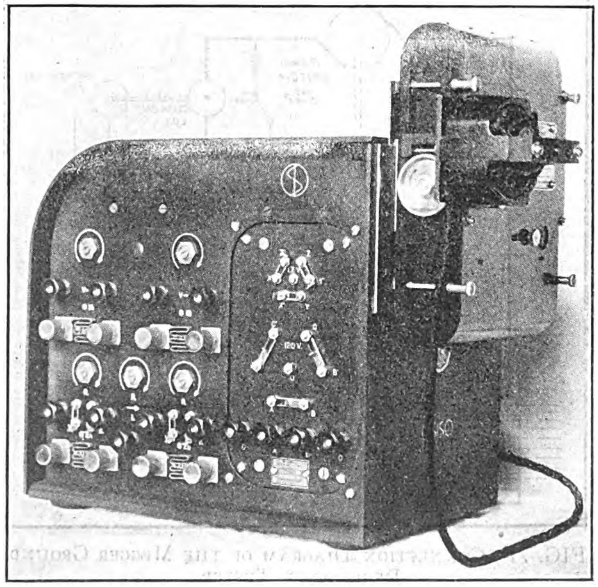

FIG. 73—POWER OSISO—ELEMENT CONTROL PANEL.

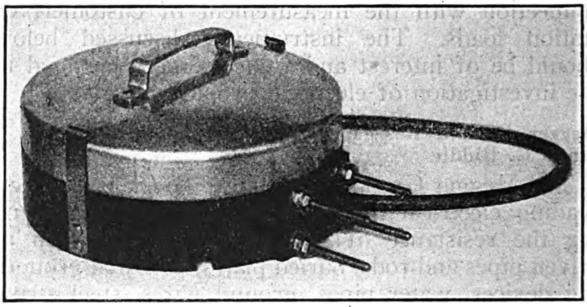

FIG. 74—SINGLE-PHASE KLYDONOGRAPH MADE BY THE WESTINGHOUSE ELECTRIC & MFG. CO.

Tachometer Generator Made by The Esterline-Angus Co.

Fig. 76 and 77 are two views of a new Tachometer Generator manufactured by the Esterline-Angus Company. This generator can be directly connected to shafts revolving at speeds up to 4000 r.p.m. The voltage generated is directly proportional to the speed of the shaft. This voltage value may be recorded on a graphic voltmeter which has been calibrated in units of speed.

It is claimed by the maker that the speed-voltage characteristic of this device is a straight line from zero r.p.m. to approximately 4000 r.p.m. It is also claimed that due to its ruggedness the device needs practically no maintenance for long periods of time.

Type D-2 Automatic Time Switch Supplied by The States Co.

Some utilities have found it desirable to adopt two, and in some cases three-rate metering. Fig. 78 shows a Type D-2, 5-ampere capacity, motor driven, self-winding, fully automatic time switch so arranged that it will change over the circuit from meter "A" to meter "B" at a specified time during a 24-hour

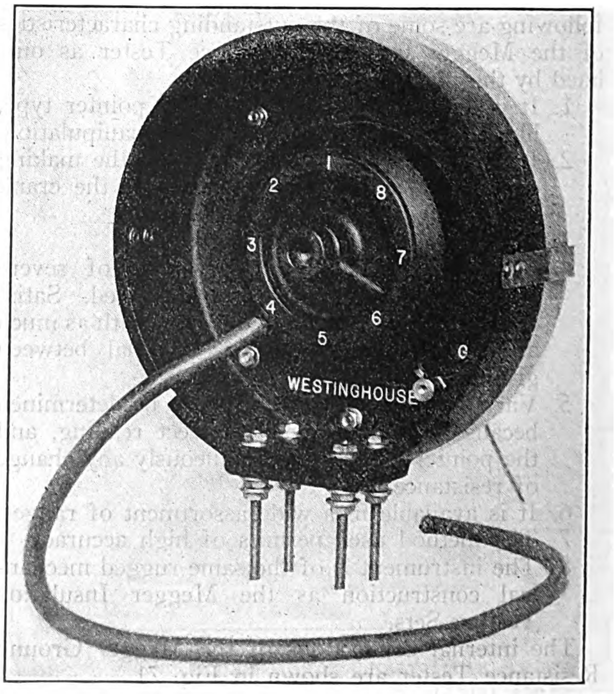

FIG. 75—SINGLE-PHASE KLYDONOGRAPH—BOTTOM VIEW.

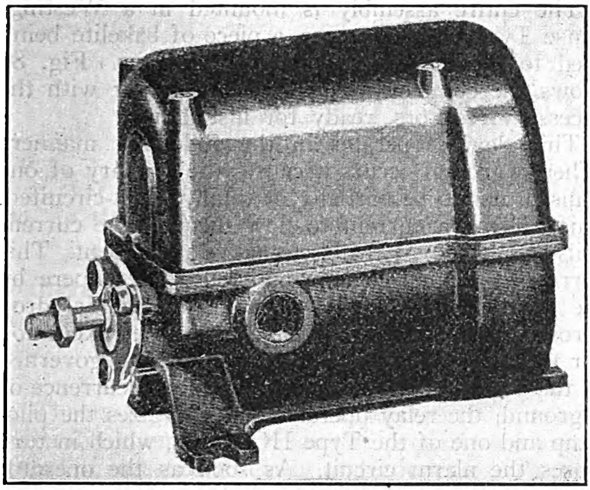

FIG. 76—TACHOMETER GENERATOR MADE BY THE ESTERLINE-ANGUS COMPANY.

period, and at a later selected time, restore the circuit to meter "A."

The manufacturer advises that switches are equipped with a high-grade watch movement having fifteen jewels. The movement is compensated for temperature changes, and has a reserve running capacity of about three days. The movement itself requires no oiling. The motor used in these switches has no brushes, no revolving armature, and no make or break contacts.

The Type D-2 two-rate meter switches may be equipped with a so-called "Sunday Cutout." This is normally a seven-day dial, but may be so set as to suspend the change over operation from one meter to the other during one or two days of the week, for example, from Saturday noon to Monday morning.

Relay Ground Detector Made by the Buffalo General Electric Co.

The Buffalo General Electric Company of Buffalo, N. Y., is using a ground detector that was developed and constructed by its Meter Department, and which, according to the report of this company, is functioning satisfactorily. The device is capable of giving an audible signal to announce the occurrence of a ground, of indicating the phase that is grounded, and of showing the extent of that ground. It is constructed chiefly of standard parts manufactured for other purposes by the General Electric Company and the Westinghouse Electric & Manufacturing Company.

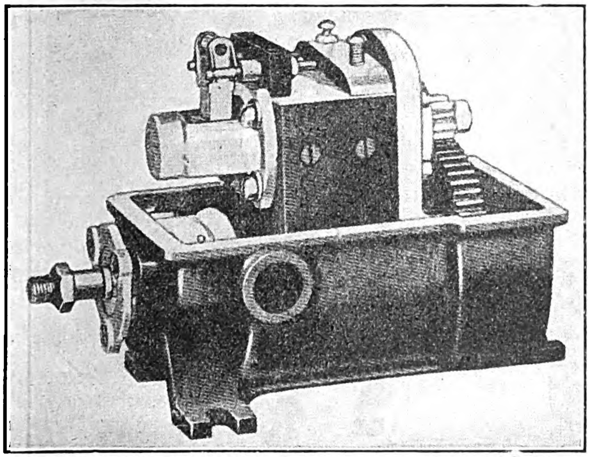

FIG. 77—ESTERLINE-ANGUS TACHOMETER GENERATOR—COVER REMOVED.

A schematic diagram of this device is shown in Fig. 79. Three instrument potential transformers of suitable rating are connected in "Y" to the high voltage system. A current limiting resistor is connected in series with each transformer, and the neutral point is grounded. The secondary, or low voltage windings, are delta connected through a 175-ohm resistor and the current coil of the ground detector relay connected in series. An indicating lamp is connected across each transformer secondary winding and located in any convenient place on the switchboard. The relay proper is constructed of the following parts:

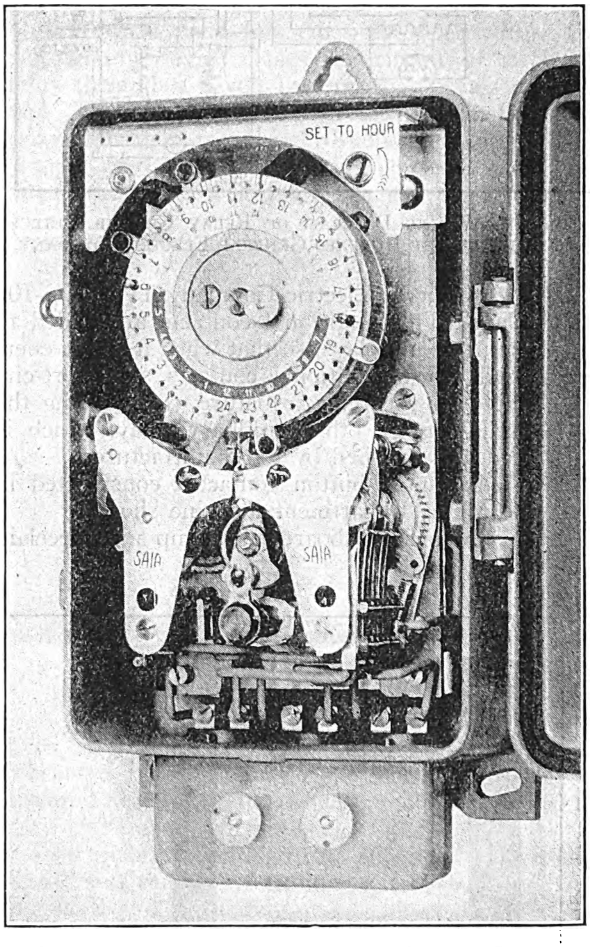

FIG. 78—TYPE D-2 AUTOMATIC TIME SWITCH SUPPLIED BY THE STATES COMPANY.

1. The directional element of a Westinghouse Electric & Manufacturing Company Type CR relay. The current coils are rewound with 180 turns of No. 24 enameled wire. The rest of the element is used unaltered.

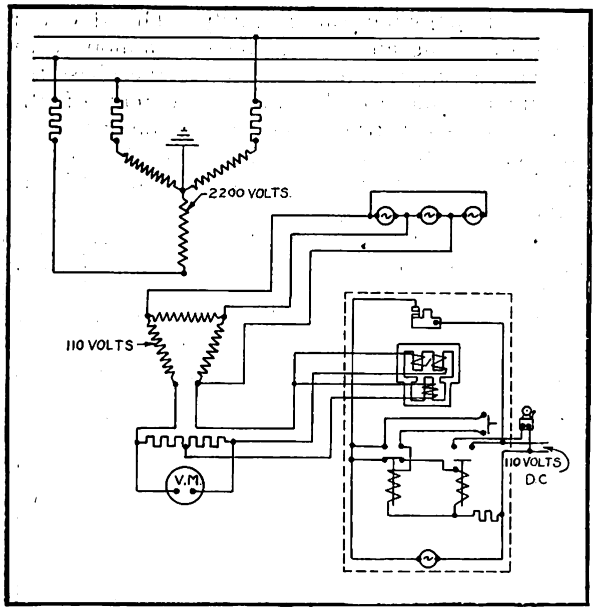

FIG. 79—Wiring Diagram of Relay Ground Detector Built by the Buffalo General Electric Company.

2. Two General Electric Company Type HG-101 relays. Two additional contacts are added to one of these relays, so that when it is not energized, these additional contacts are short-circuited by the relay armature, thus closing the circuit of the other auxiliary relay, which is used as furnished by the manufacturer.
3. A small push-button contactor constructed in the Meter Department machine shop.
4. A regular switchboard pilot lamp and porcelain receptacle.

The entire assembly is mounted in a Westinghouse Type CR relay case, a piece of bakelite being used to mount the Type HG-101 relays. Fig. 80 shows the complete relay device, together with the necessary resistors, ready for installation.

This device operates in the following manner: When a ground occurs it causes the primary of one transformer to be partially or totally short-circuited, thus causing a current to flow through the current coils of the Type CR directional relay element. This current is limited to approximately one ampere by the series resistor in the delta. The potential drop across a portion of this resistor furnishes excitation for the relay potential coil, its value being governed by the degree of the ground. Upon the occurrence of a ground, the relay operates and energizes the pilot lamp and one of the Type HG relays, which in turn closes the alarm circuit. As soon as the operator hears an alarm he closes the push-button switch and thus stops the alarm.

The pilot lamp in the relay case remains on until the ground is cleared, when the relays reset themselves automatically and the device becomes ready to announce another ground.

During a ground, one of the three indicating lamps mentioned above becomes dim or goes out entirely, while the other two become bright. By properly marking these three lamps, the grounded phase can be readily identified.

This device is claimed to be very sensitive, the degree of sensitivity being determined by the adjustment of the counter torque spring of the Type CR relay directional element. If desirable, a time lag can be introduced so that grounds of very short duration will not be announced.

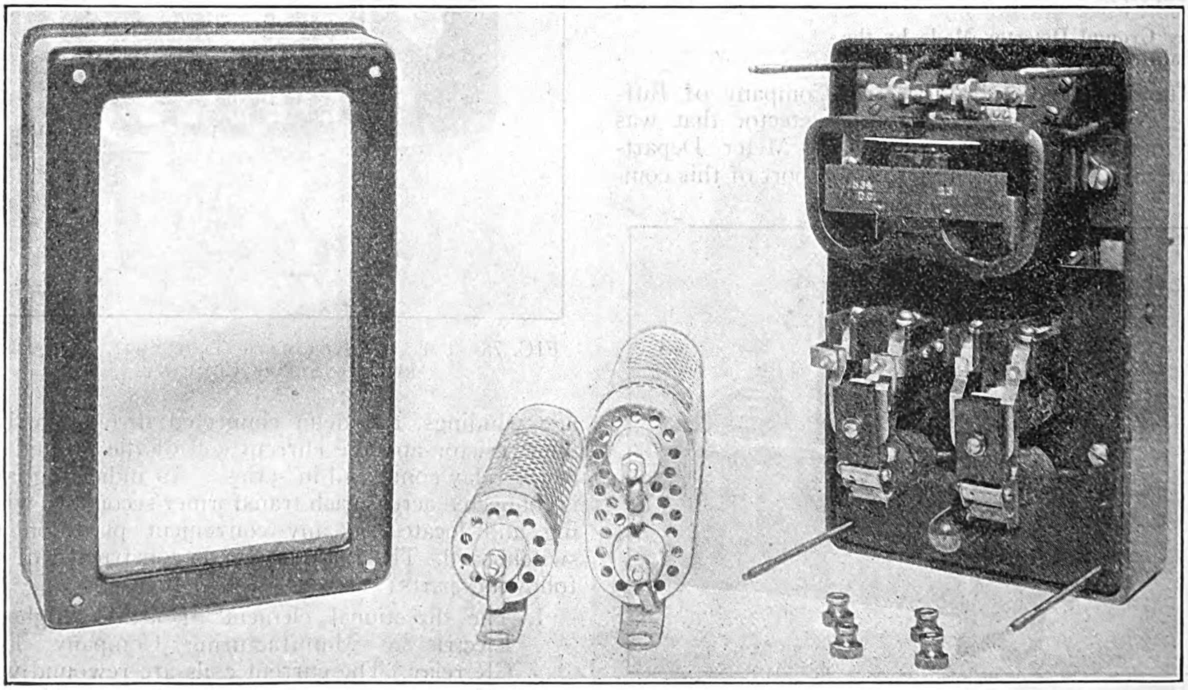

FIG. 80—Relay Ground Detector Built by the Buffalo General Electric Company.

NEW DEVELOPMENTS IN AUXILIARY TESTING EQUIPMENT

The purpose of this serial report on New Developments in Auxiliary Testing Equipment is to bring to the attention of those interested the results of a recent survey made by the Meter Committee.

No attempt has been made to verify the claims made for the devices described. Therefore, the Committee does not officially approve the various devices, but submits this material as worthy of consideration and investigation.

General

The modern electric meter department requires considerable equipment to maintain properly the various types of measuring devices under its care. Accurate standards must be available. Suitable test benches must be provided in the laboratory. Portable loading devices of various types and capacities are needed for use on customer's premises and in the generating stations and substations. There are many other useful pieces of auxiliary equipment which are essential to any well-equipped meter department, whether it be large or small. All of these are necessary if measuring devices are to be safely, accurately and economically maintained.

Realizing that many utilities have developed and built for their own use many pieces of apparatus which may be of interest and benefit to others, a special effort has been made to collect such material for this report. Available new material from various manufacturers is also submitted.

The committee has endeavored to show many forms of such equipment in the several editions of the Handbook for Electrical Metermen; and in subsequent reports has described other new and useful devices. To keep this work up to date further new developments are presented in this serial report.

The Meter Committee of the Engineering National Section, N. E. L. A., hopes to publish future serial reports on this subject from time to time, and will be pleased to receive information on new and useful pieces of auxiliary apparatus suitable for the maintenance of electrical measuring equipment, whether made for the utility company's own use, or by manufacturers engaged in merchandising such equipment.

Timing Devices

In previous publications, the Meter Committee, N. E. L. A., has referred to various timing devices for use in the testing of rotating standards and service meters. The measurement of accurate time intervals is such an important factor in the testing of metering devices, that it is thought worthy of further consideration.

Rotating Standard Timing Device Developed by The Commonwealth Edison Company

The device illustrated in Fig. 1 may be described as a relay-operated time switch for use in testing rotating standards. It operates in the following manner:

A Howard pendulum clock equipped with a control-making device closes the circuit of a 50-ohm relay through a 6-volt battery at intervals of 1 second. This relay closes the circuit of a small solenoid relay operated from a 110-volt d-c. supply. The plunger of this solenoid relay operates a pawl which in turn advances a 96-tooth ratchet wheel 1 tooth or 1/96 of a revolution each second. This device is prevented from coasting by a second pawl, operating on a second ratchet wheel attached firmly to the same shaft as the first wheel.

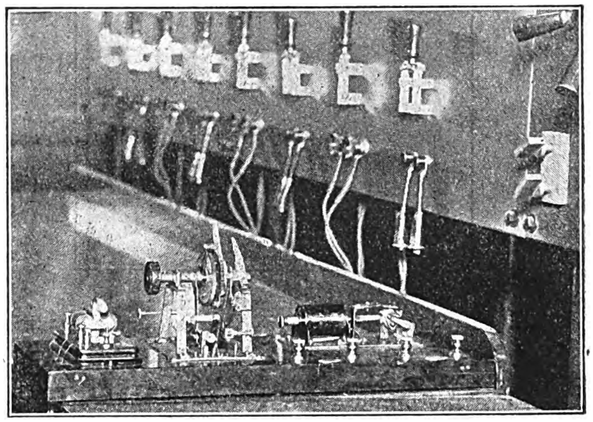

FIG. 1—Rotating Standard Timing Device Developed by the Commonwealth Edison Company.

Two insulated and adjustable arms with contact surfaces at their ends extend radially outward from this shaft and alternately make contact between fixed contacts every 60 and 36 seconds.

An electrically operated switch is operated by these contacts attached to the shaft. This switch in turn closes or opens the potential circuits of the standard meters under test. The 60-second interval is generally used for the period of test, while the 36-second interval is used as the period for observing and recording data about the instruments under test.

Personal error and certain stop-watch errors can be eliminated by the use of this device.

Timing Device Made by the Standard Electric Time Co. for Testing Rotating Standard Watthour Meters

This apparatus is also designed and built to meet the requirements of laboratories where rotating standard watthour meters are tested. It consists of

---

Publication No. 289-57, Serial Report, Meter Committee.

a high-grade, 60-beat, self-winding, electric master clock, as shown in Fig. 2, and a special make-and-break relay. The relay is actuated once every minute by impulses from the master clock so that the contacts of the relay are alternately closed for one minute and open for one minute.

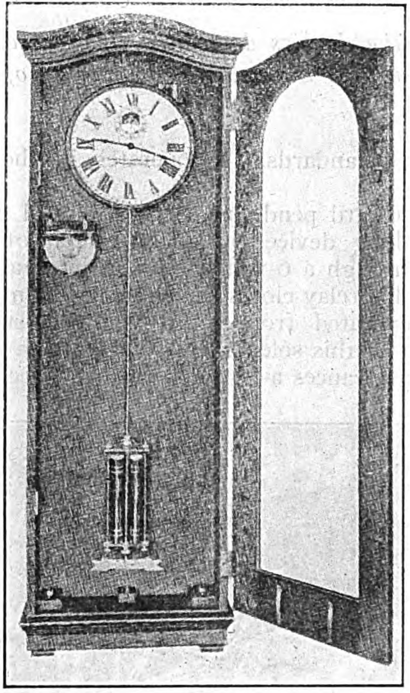

FIG. 2—TIMING DEVICE MADE BY THE STANDARD ELECTRIC TIME COMPANY FOR TESTING ROTATING STANDARD WATTHOUR METERS.

One of the impulse contacts of the master clock is mounted on the escapement wheel staff and revolves once every 60 seconds. The other contact is mounted on the verge staff and oscillates simultaneously with the pendulum. Wiping action at the contacts is thus obtained, which occurs once every revolution of the escapement wheel. The make-and-break relay, shown in Fig. 3, is of rugged construction, having contacts made of ¼ in. diameter tungsten. It is capable of breaking the potential circuit of watthour meters at 115, 230 or 460 volts, therefore no additional auxiliary relays are necessary. When voltages over 115 volts are used, it is advisable to mount the relay in a separate steel cabinet furnished for that purpose.

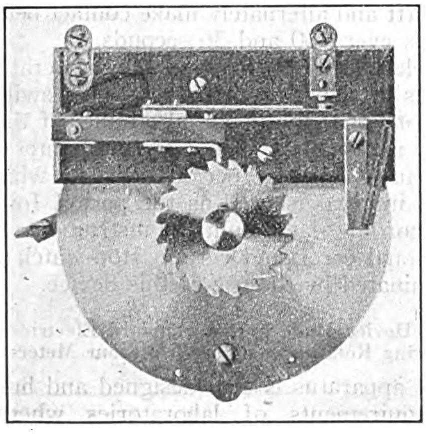

FIG. 3—CAM WHEEL FOR CLOCK SHOWN IN FIG. 2.

As shown in Fig. 3, a cam wheel is arranged in such a manner that a contact arm is alternately raised and lowered by successive impulses from the master clock. This action alternately closes and opens the meter potential circuit.

A set-up key and switch are placed within the reach of the tester so that the potential supply to the rotating standard can be controlled manually if desired.

Contact-Making Devices for Automatic Timing Equipment

Automatic timing devices are frequently operated by means of some form of contact-making device actuated by the pendulum of a second beating high-grade laboratory clock. Care must be exercised in order to prevent added friction in the clock itself and to assure uniform timing. In some contact-making devices the interval between successive contacts is not constant. In others the contact-making device requires considerable maintenance, and may interfere with the operation of an otherwise excellent clock.

To eliminate such difficulties arising from mechanical contact between the pendulum and the auxiliary devices, schemes have been developed where a beam of light fulfills this function.

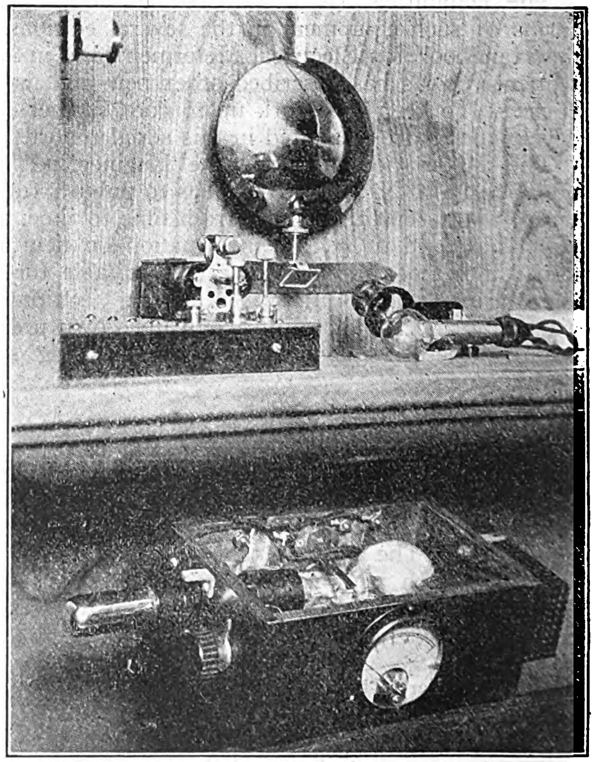

FIG. 4—PHOTO-ELECTRIC CELL ATTACHMENT DEVELOPED BY THE BUFFALO GENERAL ELECTRIC COMPANY.

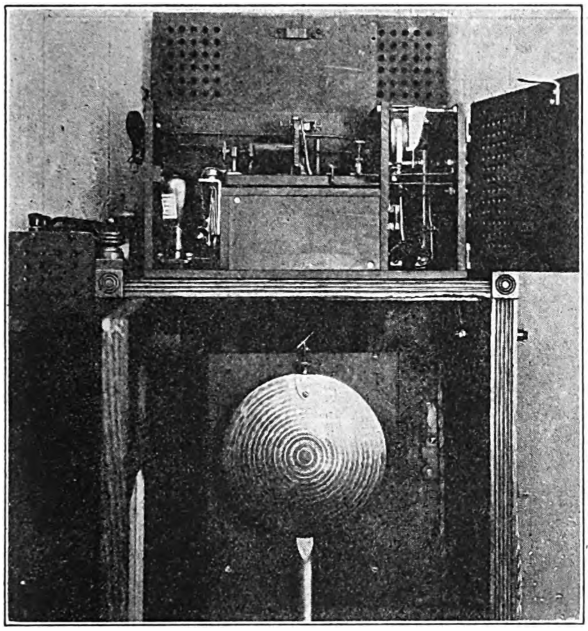

FIG. 5—PHOTO-ELECTRIC CELL ATTACHMENT ASSEMBLED BY THE NEW YORK EDISON COMPANY.

Photo-Electric Cell Attachment Developed by The Buffalo General Electric Company

In this device, electrical impulses are controlled through the medium of a photo-electric cell as shown in Fig. 4. The cell is located in a suitable container fastened to the bottom of the case of a master seconds pendulum clock. A hole has been drilled in the case of the clock just above the photo-electric cell and in line with the seconds pendulum. A small mirror fastened to the pendulum reflects the light of an ordinary automobile lamp down through this hole and on to the photo-electric cell. This momentarily energizes the photo-electric cell, causing the plate current of a radio amplifying tube to increase in value and operate a sensitive relay. This relay in turn operates a second relay, the contacts of which are capable of carrying sufficient current to operate the automatic timing equipment. This latter equipment is described in detail in Publication 25-28, Report of the Meter Committee, N. E. L. A., for 1924-1925, and also in Publication 267-92, a serial report on Auxiliary Testing Apparatus, published in July, 1927.

Photo-Electric Cell Attachment Assembled by The New York Edison Company

A device similar to the one just described has been assembled in the Meter Department of The New York Edison Company and has been in service for about a year. Fig. 5 shows a general view of this device, while Fig. 6 shows the diagram of connection used.

All the component parts of this equipment are standard stock products. The use of the 171-A type of tube eliminates the necessity of using extra sensitive relays.

Test Table Facilities

Both manufacturers and a number of utilities have built various types of special equipment to facilitate the rapid testing of meters in the laboratory. In addition to such equipment, a number of utilities have built test tables of special design to satisfy their particular need. A number of utilities find the fixed or non-portable test table most desirable, while others find that the portable table lends itself well for use inside the laboratory, as well as for work in the field.

Current Transformer Testing Bench Developed by The Union Gas and Electric Company

Fig. 7 shows a special bench, built and used by the Meter Department of the Union Gas & Electric Company, for testing current transformers. The two large V-shaped clamping devices on the bench are designed to receive the primary terminals of various sizes of current transformers. The transformer to be tested is shown on the left in Fig. 7, while the standard transformer is on the right. The secondary terminals of the current transformers are connected, by flexible leads, to the proper terminals on the panel, which in turn are permanently connected to a Silsbee Current Transformer Testing Set made by the Leeds & Northrup Company and located on another bench. Attached to the front legs of the bench are two small panels upon which fuses for the loading transformers are mounted. Additional binding posts are provided to connect transformers which cannot be accommodated by the clamping devices on the bench.

Three transformers and two induction regulators, located under the bench, can furnish any desired current value up to 6000 amperes. The panel at the rear is equipped with terminals for connecting the desired burden to the current transformer under test. Plugs and switches are provided to select any combination of loading transformer and voltage regulator coils, and thus cover the entire range of the equipment. The full secondary no-load voltage of the 6000-ampere loading transformer is about 2.3 volts.

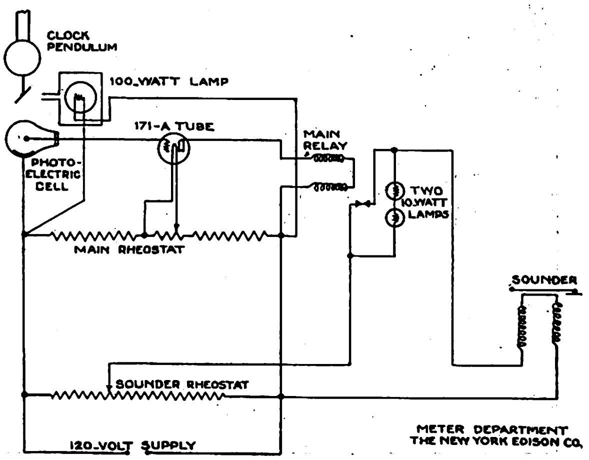

FIG. 6—DIAGRAM OF CONNECTIONS FOR DEVICE SHOWN IN FIG. 5.

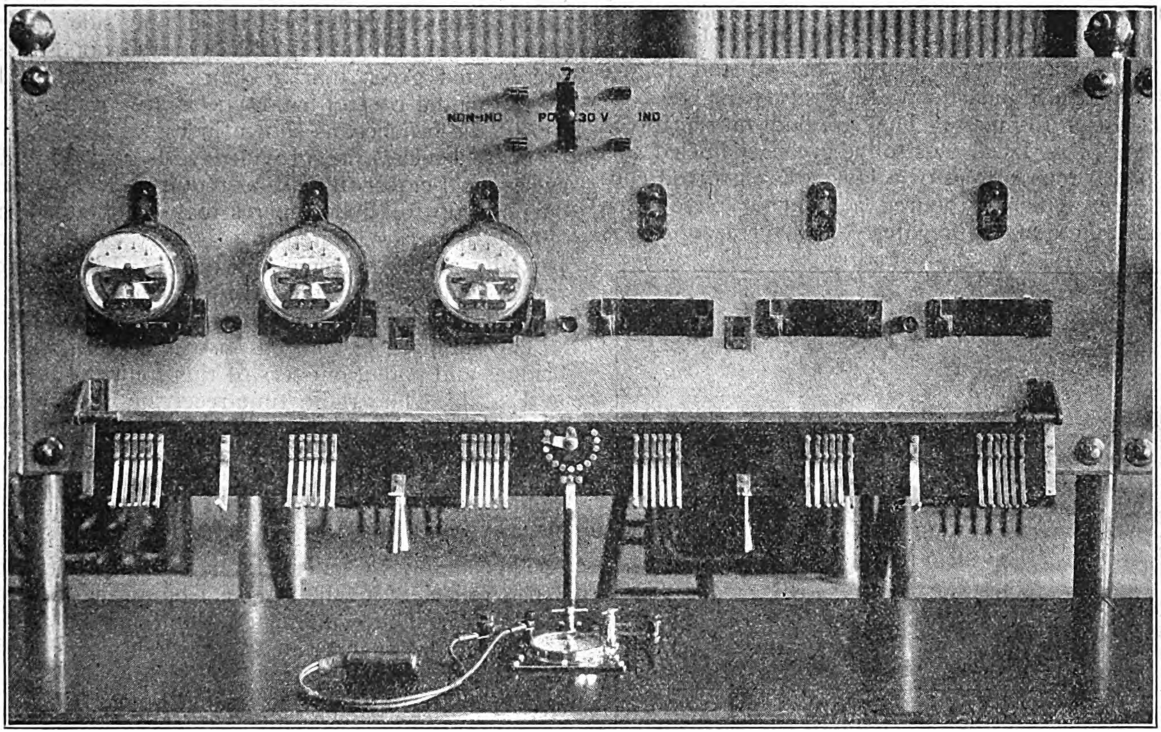

FIG. 9—CLOSE VIEW OF ONE OF THE PANELS SHOWN IN FIG. 8.

Speed Board Developed by The New York Edison Company

Fig. 8 shows a meter testing board developed by The New York Edison Company for testing various types of watthour meters. This type of board eliminates the necessity of making wire connections between the meters and the test supply. Six meters are mounted on each test panel and the hinged terminal board is swung into the working position, making electrical connections through flexible finger type contactors. Fig. 9 shows the details of the hinged terminal board and the flexible contactors which fit over the meter terminal screws when the terminal chamber cover is removed.

Potential is supplied to the six meters simultaneously as soon as the terminal board is swung up. The current circuits are controlled individually through the selector switch mounted at the center of the hinged terminal board.

A rotating test standard is placed into an opening shown in the foreground of Fig. 9 and is used for testing the six meters that can be installed on the test panel.

Tesco Quick Connector Block Made by The Eastern Specialty Company

A convenient appliance for the meter testing laboratory is shown in Fig. 10. It is designed to make possible the speedy connection of watthour meters for test. It is adjustable, and it is claimed that it will fit all types of bottom connected meters. Braided copper ribbon is used to make connections between the four (4) meter terminals of the test device and terminals located on the test panel, not shown in photograph. It is furnished complete with adjustable parts, bakelite plate for leveling, and connection block.

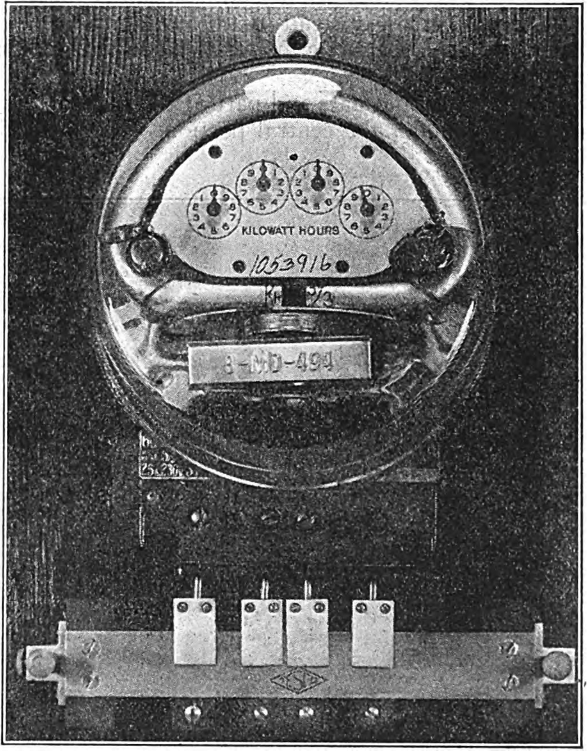

FIG. 10—TESCO QUICK CONNECTOR BLOCK MADE BY THE EASTERN SPECIALTY COMPANY.

Test Benches Designed by The New York Edison Company for Testing A-C. and D-C. Portable Test Instruments and for Maintaining Primary and Secondary Standards

The benches shown in Fig. 11, 12 and 13 are located in the Standardizing Laboratory of The New York Edison Company. They are built on reinforced concrete piers faced with olive-green enameled tile. The bench tops consist of a layer of reinforced concrete over which is poured a layer of olive-green terrazzo-alundum aggregates. The terrazzo top is polished to give a pleasant-looking and rugged working surface. The bench tops are edged with a band of angle brass, lacquered on the outer surface to match the green tile. Tobin Bronze is used throughout for reinforcing instead of the usual iron rods in order to keep magnetic materials away from the instruments.

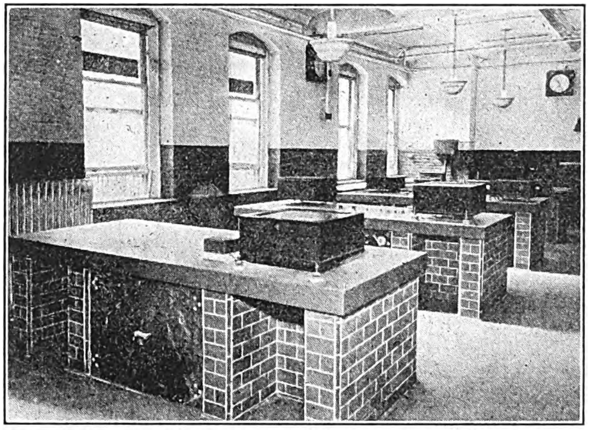

FIG. 11—GENERAL VIEW OF INSTRUMENT TEST BENCHES IN THE STANDARDIZING LABORATORY OF THE NEW YORK EDISON COMPANY.

The loading rheostats and part of the control gears are located under the central portion of each bench. Switches and control handles are mounted on green marble switchboards located on one side of each bench, as shown in Fig. 12. On the opposite side are located green marble doors, as shown in Fig. 11. Potential control hand-wheels are located on the top of the benches, as shown in Fig. 12.

These benches are provided with a-c., 25 and 60 cycles, or d-c. test supplies as required. Heavy direct-currents up to 1500 amperes may be obtained from storage batteries located in a battery cabinet shown partially at the extreme left of Fig. 12. This current is controlled by the multiple hand-wheels at the upper left corner of the switchboard in Fig. 12.

The standard test bench on which are located the bridges and potentiometers of this company is shown in Fig. 13. The radio time-receiving set is located on this bench immediately below the pendulum master clock.

Multi-Range Current Transformer Testing Table Made by Otto A. Knopp

This equipment supersedes and supplements earlier types reported in the Meter Committee report of 1924-1925. The equipment is built in two units:

1. For testing current transformers of 5 to 500-ampere capacity.
2. For testing current transformers of 600 to 3000-ampere capacity.

1. *The 5 to 500-Ampere Unit*

This unit has the following primary current ratings: 5, 10, 12½, 15, 20, 25, 30, 40, 50, 60, 75, 80, 100, 125, 150, 160, 200, 250, 300, 400 and 500 amperes. It is complete in every respect for testing the ratio and phase angle of current transformers within the above limits. It embodies a current supply transformer, multi-range standard current transformer, rheostats, instruments, switches and a panel. The entire equipment is mounted on a bench, as

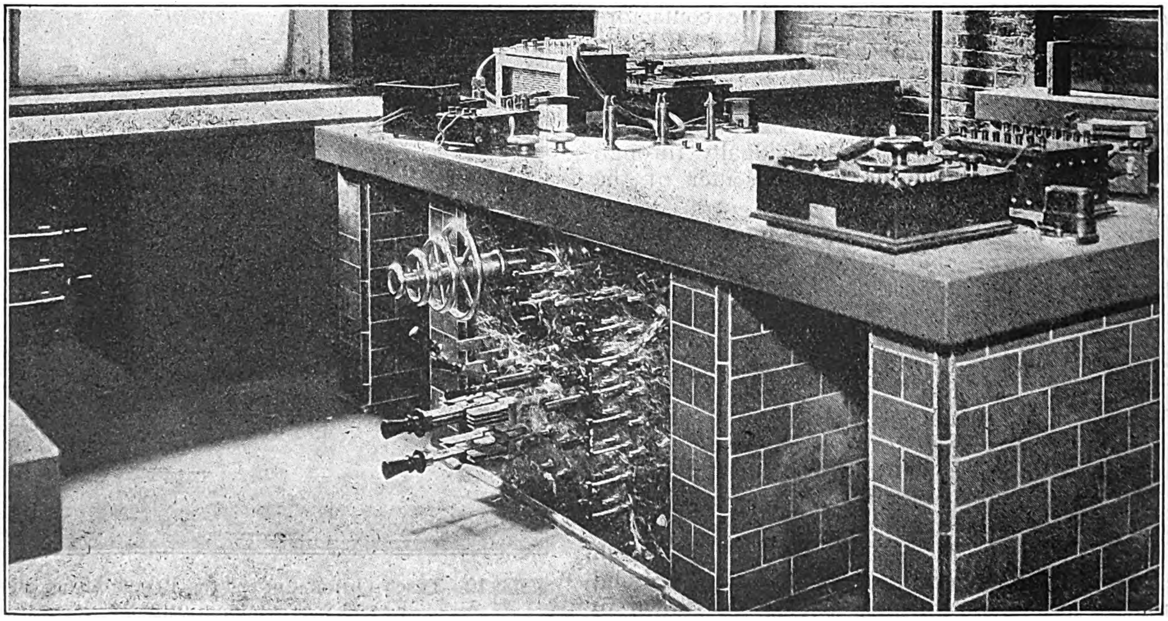

FIG. 12—CLOSE VIEW OF INSTRUMENT BENCH SHOWING CONTROL SWITCHBOARD.

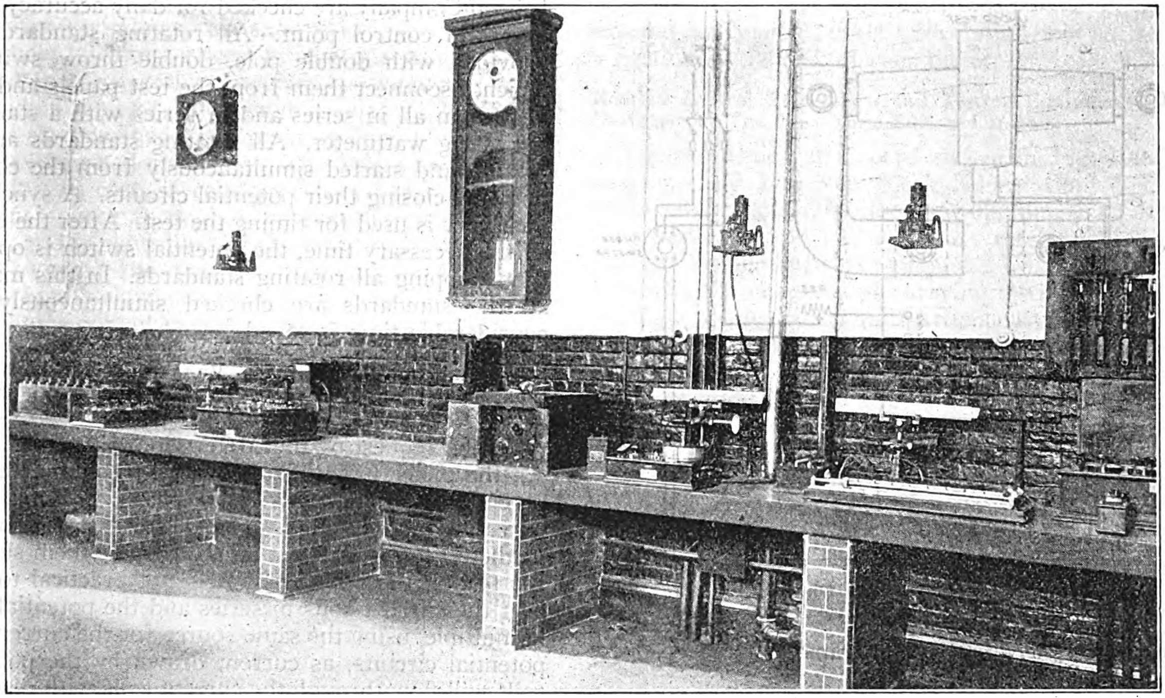

FIG. 13—STANDARD TEST BENCH IN THE STANDARDIZING LABORATORY OF THE NEW YORK EDISON COMPANY.

shown in Fig. 14, and is ready for connection to a three-phase, 220-volt, supply.

The designer claims that the standard multi-range current transformer is of such design that the ratio and phase angle corrections are the same for all ranges. It is also claimed that with this unit it is possible to determine these corrections without any reference standard, by calibrating it against itself.

A Silsbee current transformer testing set manufactured by the Leeds & Northrup Company can be used, but is not necessary, as the Silsbee deflection method can be used. This latter method was discussed in a previous serial report of the Meter Committee entitled "Auxiliary Testing Apparatus" and known as Publication No. 267-92 of the N. E. L. A.

2. *The* 600 *to* 3000-*Ampere Unit*

This unit has the following primary current ratings: 600, 750, 800, 1000, 1200, 1500, 2000, 2500 and 3000 amperes. It is built into a compact unit about 10 in. x 10 in. x 11 in., and includes a loading transformer, as shown in Fig. 15. While it is a complete unit in itself, it could very well be mounted upon a test table with the smaller equipment described above.

A maximum current of 5 amperes is drawn from a 220-volt, 3-phase supply. This is transformed to the proper current value by means of a step-up transformer, which is a part of the equipment. This unit is wired to permit the use of the Silsbee deflection

Standard Checking System Developed by The New York Edison Company

The rotating test standards located on the meter testing panels in the laboratories of The New York Edison Company are checked for daily accuracy from a central control point. All rotating standards are provided with double pole, double throw switches, which disconnect them from the test panels and connect them all in series and in series with a standard indicating wattmeter. All rotating standards are set to zero and started simultaneously from the control point by closing their potential circuits. A synchronous timer is used for timing the test. After the elapse of the necessary time, the potential switch is opened, thus stopping all rotating standards. In this manner all the standards are checked simultaneously and considerable time is saved.

Equipment Developed by The Buffalo General Electric Company for Series Testing of Single-Phase, Watthour Meters Without the Use of the Potential Test Links

At the request of the Meter Committee, N. E. L. A., the meter manufacturers recently eliminated the potential test link from single-phase, 115-volt, two-wire, watthour meters. This requires an alteration of the present series test tables to make them suitable for testing these meters. It is not practical to connect the current coils in series and the potential coils in multiple, using the same source for the current and potential circuits, as current drawn by the potential coils will flow through the current coils with resulting inaccuracy in testing. It is, therefore, necessary to have a separate potential source for each meter.

The Buffalo General Electric Company uses a modification of the start and stop method described in Chapter VI of the Handbook for Electrical Metermen. The main feature of the modified method is the use of a special potential transformer having

FIG. 17—EQUIPMENT DEVELOPED BY THE BUFFALO GENERAL ELECTRIC COMPANY FOR SERIES TESTING OF SINGLE-PHASE WATTHOUR METERS WITHOUT THE USE OF POTENTIAL TEST LINKS.

one primary winding and sixteen carefully balanced secondary windings, as shown in Fig. 17. Each secondary winding, excepting the one which is connected to the rotating standard, is connected to an individual meter (A) through a relay (C). Fifteen relays are provided, the operating coils of the group being connected in series. The operating coil circuit, in this case, is connected to a 115-volt, direct-current source through a current limiting resistor, (R_1), and is controlled by the usual type of potential snap switch. The closing or opening of this switch operates all relays simultaneously, and automatically starts or stops all meters under test.

A modified standard Model T Ford generator relay is used. It is very positive in its action. Fig. 18 shows this relay with cover removed.

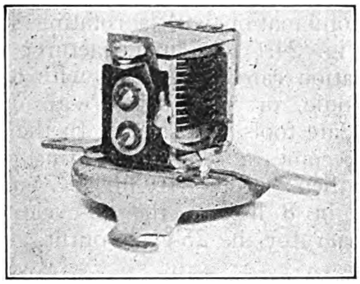

FIG. 18—CLOSE VIEW OF RELAYS "C" SHOWN IN FIG. 17.

When the snap switch is closed, the relays (C) close the individual potential circuits of the meters under test. The switch is allowed to remain closed during the proper number of revolutions of the standard to give correct registration for two, ten or twenty revolutions of the meters under test. The snap switch is then opened, and the relays in turn open the potential circuits of their respective meters. The accuracy of each meter is then read on a stationary card marked in 0.01 revolution, and encircling a portion of the disk of each meter.

Remote Control Test Board and Testing Equipment Designed by The New York Edison Company

The test bench and board shown in Fig. 19 were developed by The New York Edison Company for testing relays and instruments in the new East River Generating Station. The primary reason that led to the development of this equipment was the desire to eliminate the necessity of carrying testing equipment throughout the station and particularly the spreading of the test equipment on the Control Room floor, where it would be in the way of the station operators. In addition, the use of this centrally located equipment saves considerable time in connecting and disconnecting the test equipment.

The test instruments and control devices are permanently located in the Test Room shown in Fig. 19. Connections can be made to any part of the station through the terminal board shown at the right of Fig. 19. Taking, for instance, the case of testing relays, one tester sits in the Test Room at the instruments and another tester goes to the oil circuit breaker gallery, shown in Fig. 20, where the current transformers are located. Using the proper test circuits, this tester makes test connections to the current transformer as shown in Fig. 20; he then proceeds to the Control Room where the relays are located. In Fig. 21 the tester is shown testing a three element over-current relay. He is in constant communication with the tester in the Test Room by means of the Callaphone system. The tester in the Test Room speaks into the wall set shown at the left of Fig. 19, while the tester in the Control Room carries a head set similar to that used by telephone switchboard operators.

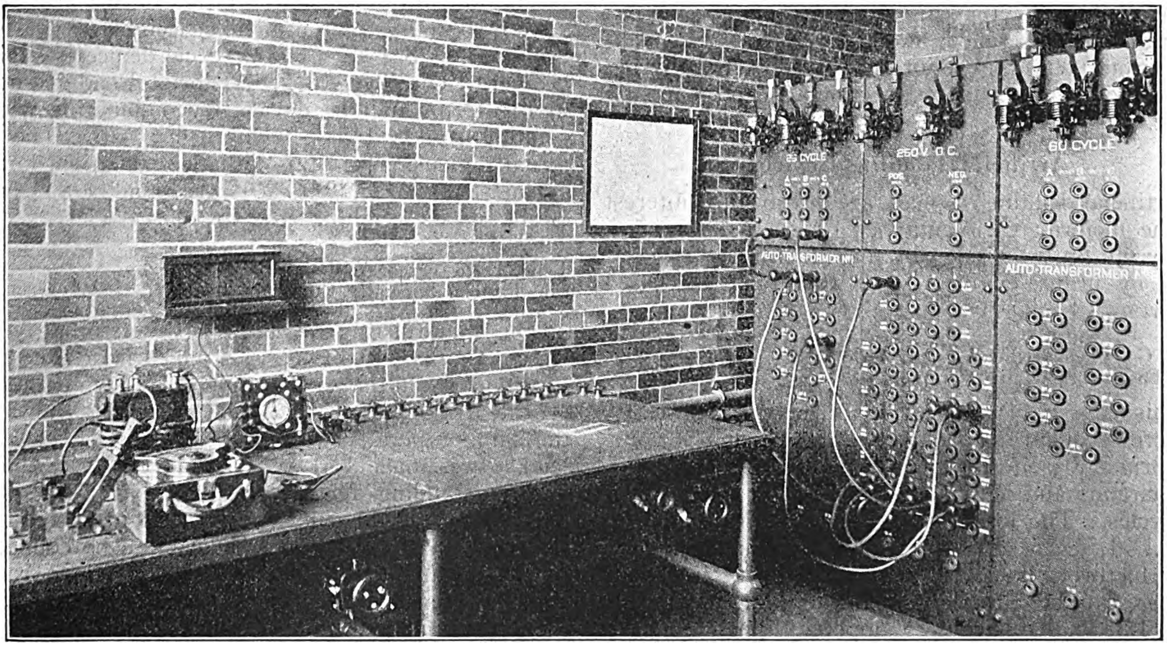

FIG. 19—REMOTE CONTROL RELAY TEST BENCH AND CONNECTION BOARD DESIGNED BY THE NEW YORK EDISON COMPANY.

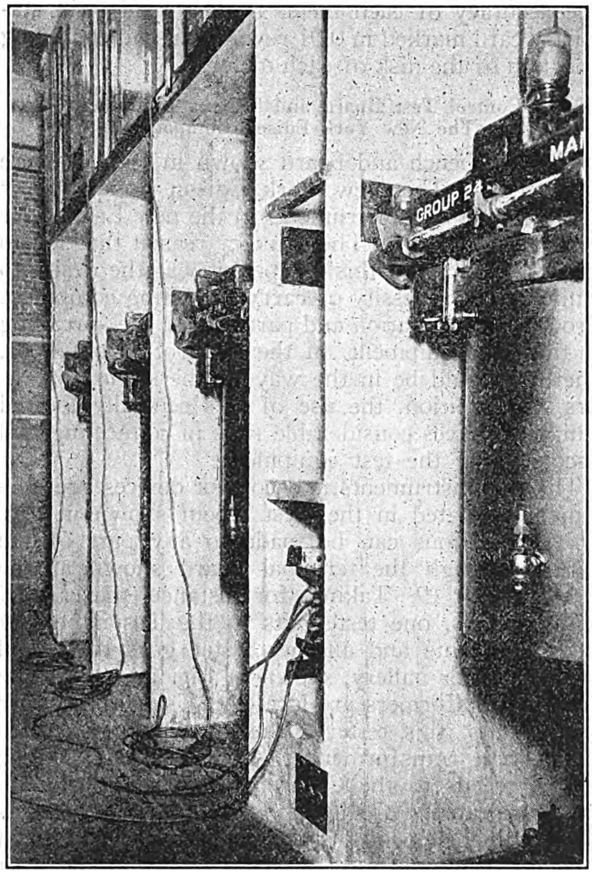

FIG. 20—HIGH TENSION GALLERY TEST CONNECTIONS MADE BETWEEN THE CURRENT TRANSFORMERS AND THE TEST STATION WHICH IS PERMANENTLY CONNECTED WITH THE CONNECTION BOARD SHOWN IN FIG. 19.

This company claims that excellent results have been obtained by the use of this equipment. Considerable time is saved, and the possibility of making wrong test connections is greatly reduced because most of the test connections are permanently made.

Artificial Loading Devices

Artificial loading devices are always of interest to the meterman. A number of such devices recently put on the market by manufacturers or developed by utility engineers are, therefore, discussed below.

Type G Tesco Artificial Load Made by The Eastern Specialty Company

This is a low voltage transformer having a 25-ampere secondary capacity at approximately 4 volts. Its primary is designed for use on 110 and 220-volt circuits and is available for use on either 25 or 60 cycles. The load ratings usually furnished are: 0.5, 1, 1.5, 2.5, 5, 10, 15 and 25 amperes. The manufacturer, however, advises that the following ratings can be furnished upon request: 0.25, 0.5, 0.75, 1.25, 5, 10, 15 and 25 amperes. The secondary load is governed by series resistors, which may be easily replaced when necessary. The manufacturer claims that this device will carry full load current continuously without damage. The device can be readily inspected and repaired when necessary.

The manufacturer also claims that the power factor of this device is 95 per cent at light load and approximately 99 per cent at full load, and that the wave form of the secondary current is practically the same as that of the impressed primary voltage.

The outside dimensions of this device are: 7 in. x 3¾ in. x 6 in. excluding the cover, and 7½ in. x 3¾ in. x 6 in. including the cover. The cover can be furnished with a carrying strap. The 60-cycle device weighs 6 lb., while the 25-cycle device is slightly heavier. Fig. 22 shows an external view of the Type G Tesco Artificial Load, while Fig. 23 shows the device removed from its case.

The Type G Artificial Load can also be furnished for use in combination with a rotating standard, as shown in Fig. 24. The manufacturer states that this combination can be supplied with a cover and carrying handle, or, if desired, with outside case to accommodate tools, leads, etc. In the latter case, this device becomes a "one-man testing outfit." Its dimensions then become 10 in. x 7 in. x 6 in., and its weight 8 lb. for the 60-cycle outfit, and slightly heavier for the 25-cycle outfit.

Type A-25 Tesco Artificial Load Made by The Eastern Specialty Company

According to the manufacturer, the Type A-25 Artificial Load has practically the same characteristics as the Type G, described above. However, the Type A-25 is of somewhat larger dimensions and weight, and has a secondary voltage of 6 volts. The primary voltage is 110/220 volts.

Load adjustment is accomplished by means of double pole switches arranged to give current values of 0.25, 0.5, 1, 2, 5, 10 and *10* amperes.

The outside dimensions of this device are: 6 in. x 6-3/16 in. x 6½ in. The weight of the 60-cycle unit is 8¾ lb. The 25-cycle device is slightly heavier. The Type A-25 Artificial Load is shown in Fig. 25, while the device, in combination with a rotating standard, is shown in Fig. 26. The external dimensions of this latter combination, known as the Type A-25, Cat. 801, are 6 in. x 8½ in. x 12 in. and its weight is 10¾ lb.

Type AS-25 Tesco Artificial Load Made by The Eastern Specialty Company

The manufacturer states that the Type AS-25 Tesco Artificial Load, Fig. 27, which is designed for a secondary output of 25 amperes at 6 volts, and to operate from a 110 or 220-volt primary supply, has the same general characteristics as the Type A-25 load. It is made for both 25 and 60-cycle service. The outstanding feature of this device is its load switching arrangement. It is so constructed that two coils of the rotating standard can be connected to the loading device simultaneously. Two rotary switches are provided, one of which is used to select the proper field of the rotating standard for a full or light load test. The other selects the proper value of test current. The manufacturer claims that, by

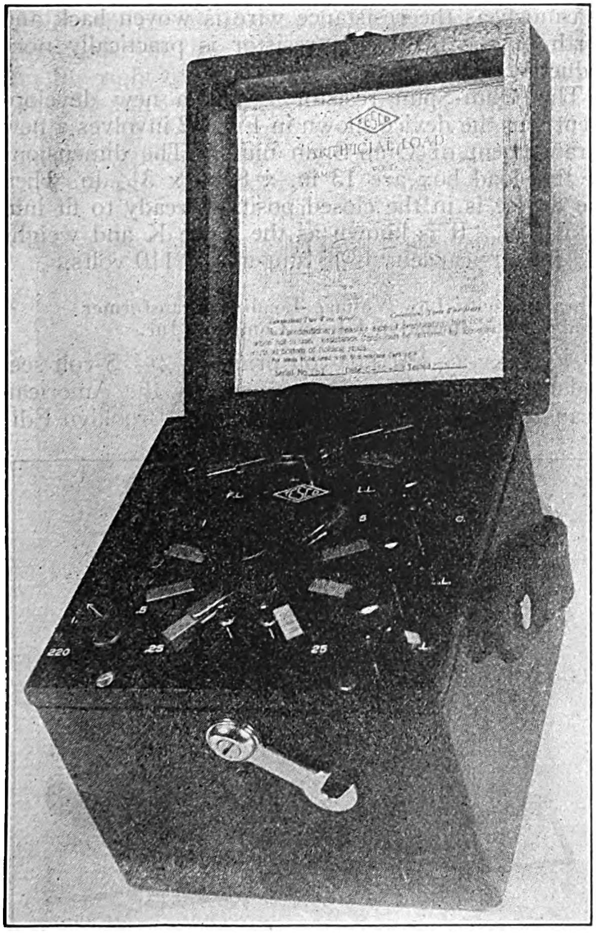

FIG. 27—TYPE AS-25 TESCO ARTIFICIAL LOAD MADE BY THE EASTERN SPECIALTY COMPANY.

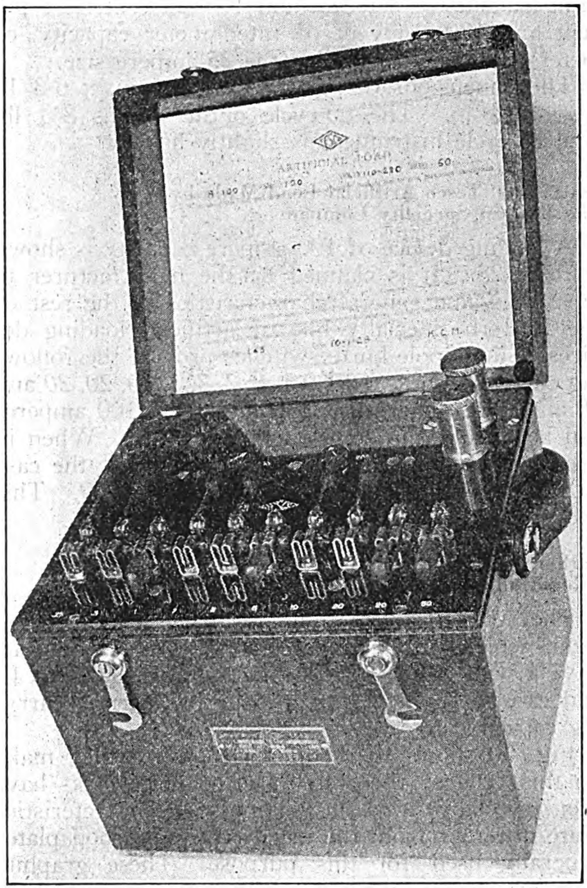

FIG. 28—TYPE A-100 TESCO ARTIFICIAL LOAD MADE BY THE EASTERN SPECIALTY COMPANY.

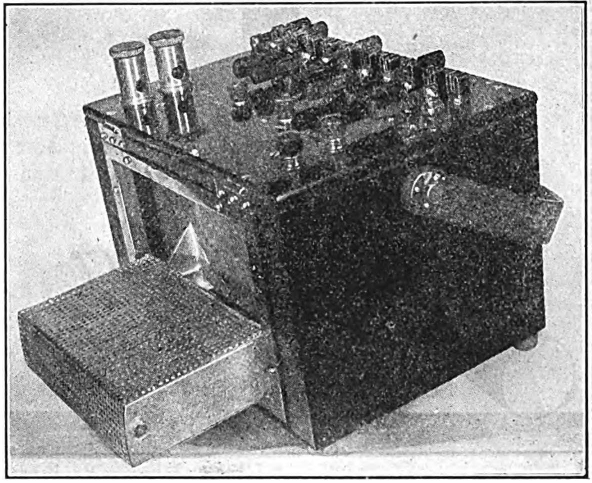

FIG. 29—SECOND VIEW OF DEVICE SHOWN IN FIG. 28.

means of this arrangement, time is saved in switching from one load to another during test, and overloading of the 1-ampere coil of the standard is prevented. Current values are provided for full and light loads at 10 per cent and 100 per cent, or 5 per cent and 100 per cent of rated meter capacity, of meters up to and including the 25-ampere size.

The dimensions of this device are 6 in. x 6-3/16 in. x 6½ in. The 60-cycle outfit weighs 8¾ lb. The 25-cycle instrument is slightly heavier.

Type A-100 Tesco Artificial Load Made by The Eastern Specialty Company

A loading device of 100-ampere capacity is shown in Fig. 28. It is claimed by the manufacturer to have the same general characteristics as the rest of the Eastern Specialty line of artificial loading devices. Single-pole knife switches provide the following current values: 0.25, 0.5, 1, 2, *2*, 5, 10, 20, *20* and 50 amperes. Therefore, currents up to 100 amperes can be obtained in steps of 0.25 ampere. When in use, the resistor unit can be swung out of the case to provide ventilation, as shown in Fig. 29. This prevents undue heating of the instrument.

Carbon Rheostats Made by The Allen-Bradley Company

The Allen-Bradley Company makes carbon rheostats, which, it claims are very flexible, durable, have a wide range of resistance (ratio of 75 to 1) and can be supplied for any desired current-carrying capacity.

Fig. 30 shows the component parts which make up this type of rheostat. The graphite disks have been specially treated and possess characteristics quite different from the usual type of carbon plates generally used for this purpose. These graphite disks are inserted into an insulated steel tube, making a very compact unit.

Fig. 31 shows a 3-tube Type E-2210 rheostat. The manufacturer states that any desired combination of these units can be furnished for any type of mounting desired.

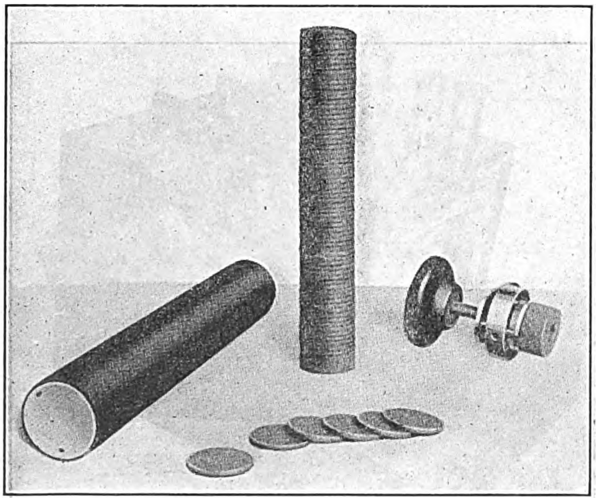

FIG. 30—CARBON RHEOSTAT UNIT MADE BY THE ALLEN-BRADLEY MANUFACTURING COMPANY.

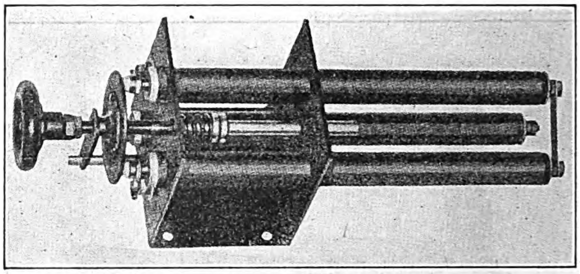

FIG. 31—A THREE-TUBE, TYPE E-2210, ALLEN-BRADLEY RHEOSTAT.

This type of rheostat has been found very satisfactory by The New York Edison Company and has been used very extensively by them. In particular, they are used in connection with the testing equipment designed by The New York Edison Company and shown in Fig. 11, 12 and 19.

Ohm-Spun Loading Device Made by The States Company

This device was designed to meet the demand for a non-inductive rheostat of compact dimensions, light in weight and rugged in construction. These resistors are built by weaving resistance wire into supporting strands of long fiber asbestos thread. Inasmuch as the resistance wire is woven back and forth in one plane, the resistor is practically non-inductive.

The Ohm-Spun resistor is not a new development, but the device shown in Fig. 32 involves a new arrangement of Ohm-Spun units. The dimensions of this load box are 13 in. x 8 in. x 3½ in. when the device is in the closed position, ready to fit into a kit box. It is known as the Type K and weighs 3⅜ lb. Its capacity is 15 amperes at 110 volts.

Large Capacity Low Voltage Loading Transformer Used by The Brooklyn Edison Company, Inc.

A 100 kv-a., 220/110-volt primary, 2½/5-volt secondary loading transformer made by the American Transformer Company is used by The Brooklyn Edi-

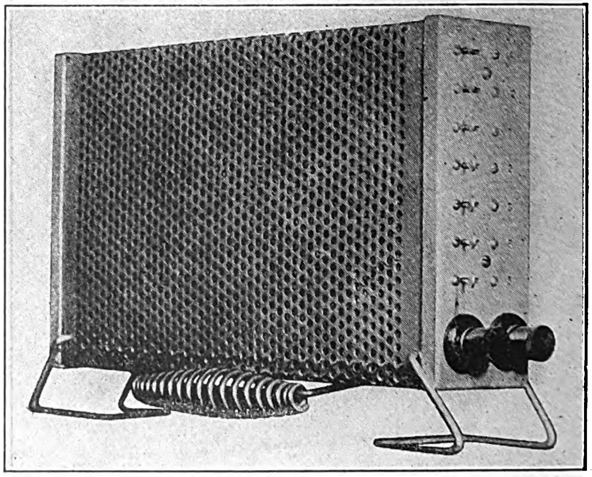

FIG. 32—OHM-SPUN LOADING DEVICE MADE BY THE STATES COMPANY.

son Company to load automatic network protectors for test. It has a maximum capacity of 20,000 amperes. Fig. 33 shows the loading transformer with its load regulating rheostat and switch panel, all mounted on a truck.

Laboratory Storage Battery Control Panel Developed by The Union Gas and Electric Co.

Fig. 34 shows a front view of a specially designed panel built to furnish a variety of series and series-parallel connections for a laboratory storage battery, and to provide charging connections. Fig. 35 is a rear view of the lower portion of the panel, with the cover of the drum switch removed.

The battery is composed of 80 six-volt, 50-ampere-hour lead storage battery units. When not in use, the battery is divided into four groups of twenty units each, to charge at a trickle charge rate from a 240-volt direct-current supply.

At the top of the panel, Fig. 34, are a 200-ampere ammeter, a multi-range voltmeter and a 10-ampere ammeter. A circuit breaker for the battery circuit is located just below the top panel. At the left of the circuit breaker is a five-position voltmeter switch. This makes possible reading separately the voltage of each of the four groups into which the battery is divided when on charge, and the voltage of the direct-current line used for charging. Just below the circuit breaker is a strap for changing the multiplier on the voltmeter. The ammeter switch at the right of the circuit breaker is used to connect the 10-ampere ammeter for reading the charging current of each group separately. The 8-P.D.T. switch is thrown "up" for charging and "down" for discharging the battery. The largest hand wheel turns the large drum switch shown in Fig. 35. It has six positions, which give the values of voltage and current ratings shown in Table I.

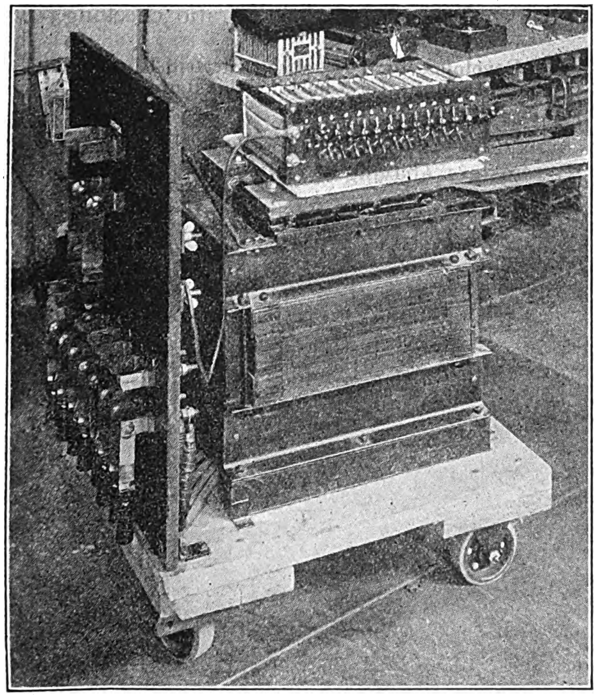

FIG. 33—LARGE CAPACITY LOW VOLTAGE LOADING TRANSFORMER USED BY THE BROOKLYN EDISON COMPANY, INC.

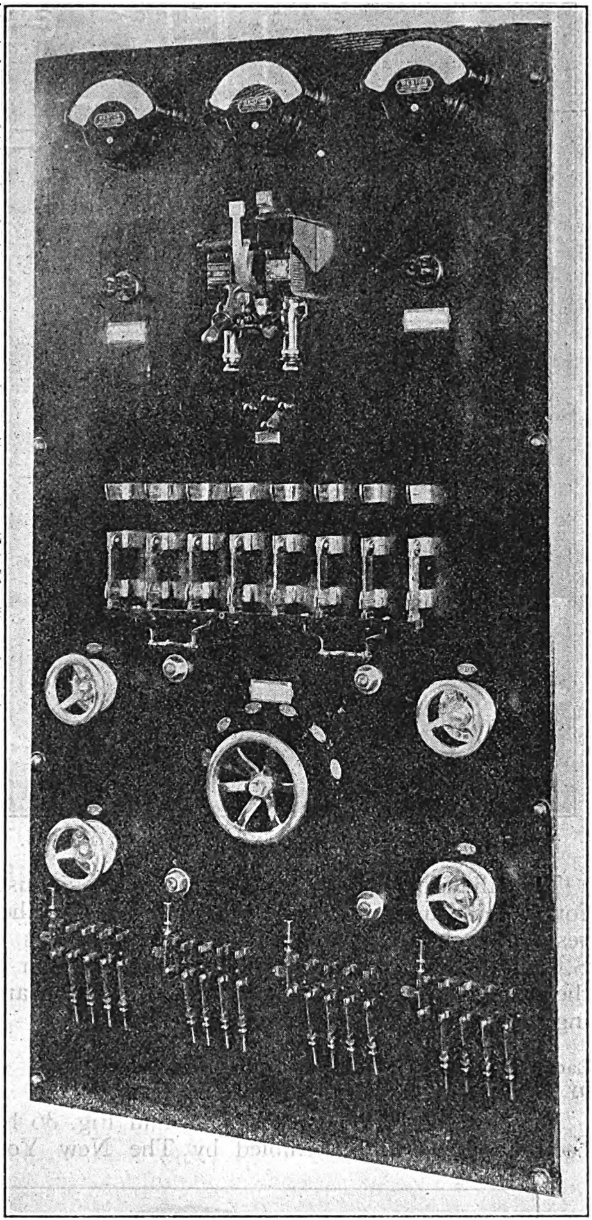

FIG. 34—LABORATORY STORAGE BATTERY CONTROL PANEL DEVELOPED BY THE UNION GAS & ELECTRIC COMPANY.

TABLE I

Position	Voltage Rating (Volts)	Current Rating (Amperes)
A	30	200
B	60	100
C	120	50
D	240	25
E	480	12.5
F	120	Charging position

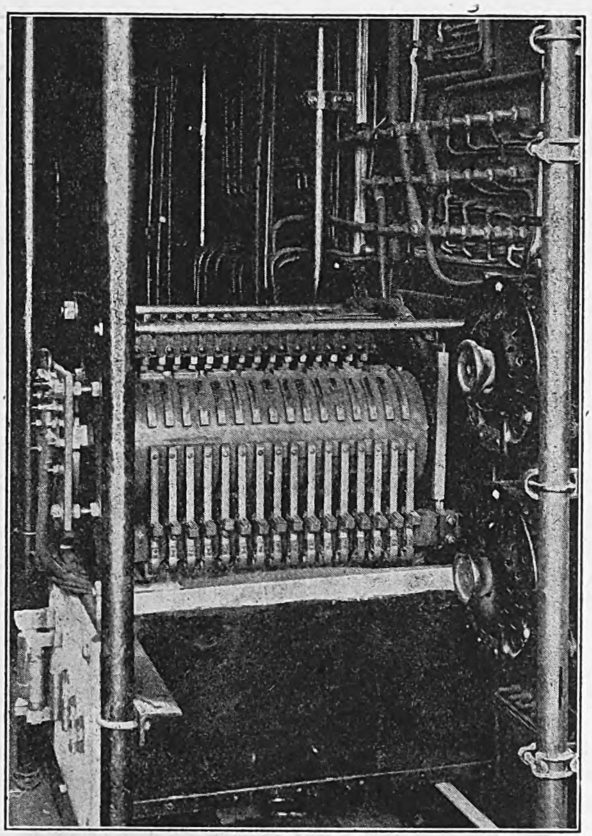

FIG. 35—REAR VIEW OF PANEL SHOWN IN FIG. 34.

The other four hand wheels operate rheostats used for close adjustment of the charging rates of their respective charging circuits. The four groups of S.P.S.T. knife switches, located at the bottom of the panel, are used for rough control of the charging rates of the four sections of the battery.

Large Capacity Portable Testing Battery Assembled by The New York Edison Company

The portable battery truck shown in Fig. 36 has been designed and assembled by The New York Edison Company for supplying test currents up to 1500 amperes. The unit consists of eight Type A-12 Edison cells.

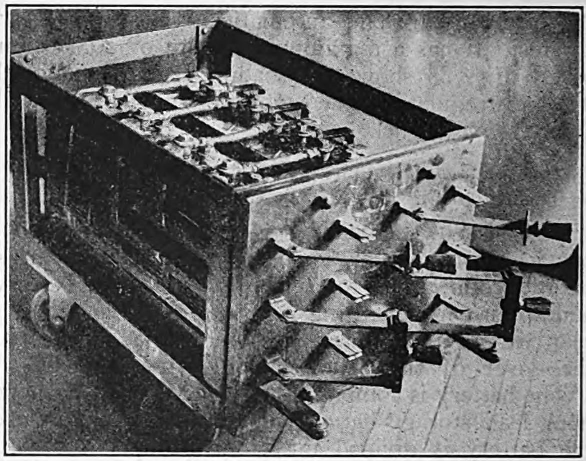

FIG. 36—LARGE CAPACITY PORTABLE TESTING BATTERY ASSEMBLED BY THE NEW YORK EDISON COMPANY.

The switchboard mounted at the end of the truck was specially designed for this purpose and affords a quick and convenient means of connecting the cells in series, parallel, or series-parallel. The copper terminals of the battery are located below the switches.

Register Checking Devices

Most companies feel that it is necessary to check all register ratios in one manner or another. Some may feel that the series testing boards give a sufficiently close check, while others may not. Some count register ratio by hand, while others provide special equipment for register ratio checking.

Device Developed by The Edison Electric Illuminating Company of Boston for Checking the Ratio of Type of Registers

This device is designed to check the ratio of Type OB registers (having a ratio of 3600), and to run

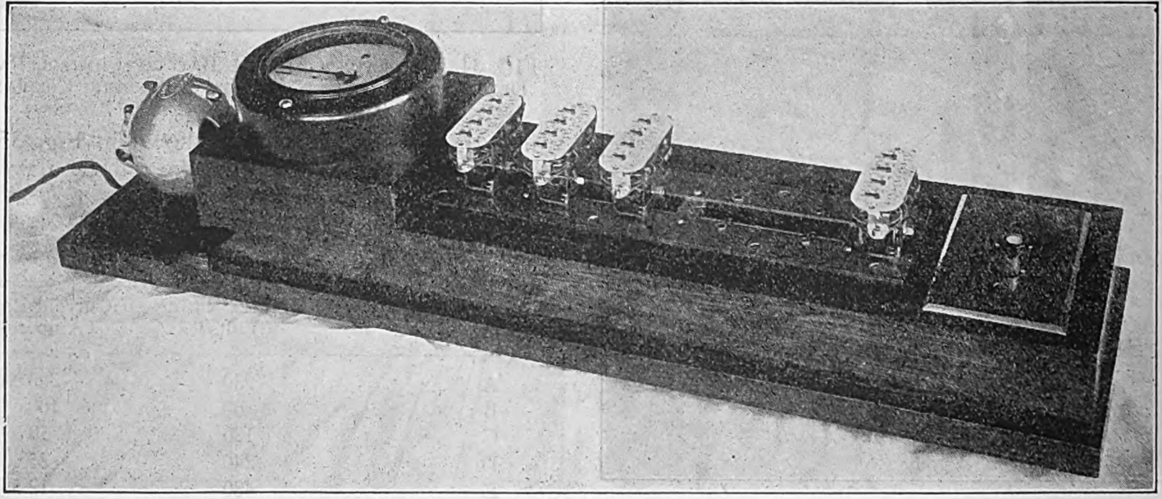

FIG. 37—DEVICE DEVELOPED BY THE EDISON ELECTRIC ILLUMINATING COMPANY OF BOSTON FOR CHECKING THE RATIO OF TYPE OB REGISTERS.

the pointers back to zero after the check. Six registers may be checked simultaneously. In the illustration, Fig. 37, two positions are left vacant to show the shaft pinions and sleeves for the register prongs. The shaft is driven by the small universal motor located at the extreme left of the device. A master register is geared to the shaft. One revolution of the pointer of the master register corresponds to a reading of 1 kw-hr. on the registers under test.

Referring to Fig. 38 the following operations are performed to make a check: the registers, reading 0000, are placed on the device, and the motor is started by throwing switch "B" to position "1," (push button switch on the extreme right of Fig. 37). When the large pointer has made one revolution, the motor is automatically stopped by switch "A," which shifts to position "2." Each register should then read exactly 1 kw-hr. To return the dial pointers to zero, the motor is reversed by throwing switch "B" to position "2." The motor is automatically stopped again by switch "A," which then moves to position "1."

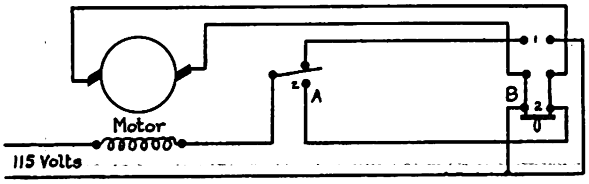

FIG. 38—WIRING DIAGRAM OF DEVICE SHOWN IN FIG. 37.

The speed of the pointer of the master register is approximately one revolution in 18 sec., which means that the time required to check registers is reduced materially by the use of this device.

Device Developed by The New York Edison Company for Checking Register Ratios

This device consists of a shaft having five gear wheels mounted in such positions that four registers may be driven at one time and checked against the fifth or standard register. A small motor supplies the driving force for the shaft, Fig. 39. With this device it is possible to check a number of revolutions of the fastest moving hand, without an excessive loss of time. The motor maintains a speed of approximately 750 r.p.m., and it is found that driving the registers at this speed causes no damage to the gear wheels. The reversing switch on the extreme right of Fig. 39 serves to reverse the motor and to run the registers in either direction.

This device is used for checking General Electric Company Type I-14, I-16 and C-15 registers.

Air-Driven Register Checking Devices Developed by The Union Gas and Electric Company

Fig. 40 shows examples of register checking devices which have proved very satisfactory to the electric meter department of the Union Gas and Electric Company. Where compressed air is available, these devices have been found much more satisfactory than motor-driven devices, and are inexpensive to construct. They are easily controlled over an extremely wide range of speeds in either direction of rotation. This company advises that no register gears have been damaged, whereas with the motor-driven equipment gears were occasionally ruined.

Types I-14 and I-16 registers are checked by using one register, with its worm-wheel removed, as a master. Its worm gear is meshed with that of the register to be checked. The two are then driven by a jet of air blown directly on the first gear of the register. Other types use a turbine wheel, which drives a gear, with which both the master register and the register to be checked are meshed. On each device one register of the type to be checked, having first been checked by inspection, is used permanently as a standard.

Miscellaneous Devices of Interest to Metermen

A number of miscellaneous tools, devices and equipment of interest to metermen are discussed below. They are of such a varied nature that they do not seem to fall under any of the previous classifications.

Micrometer Full Load Adjustment Developed for Rotating Standards by the Pacific Gas and Electric Company

It is thought by the Pacific Gas and Electric Company that the present full load adjusting devices on rotating standards are too coarse to permit close adjustment of the standards without spending an undue amount of time. Accordingly, they have fitted their standards with a simple and effective device for a micrometer adjustment of the full load speed. As a rule, when the magnet clamping screws

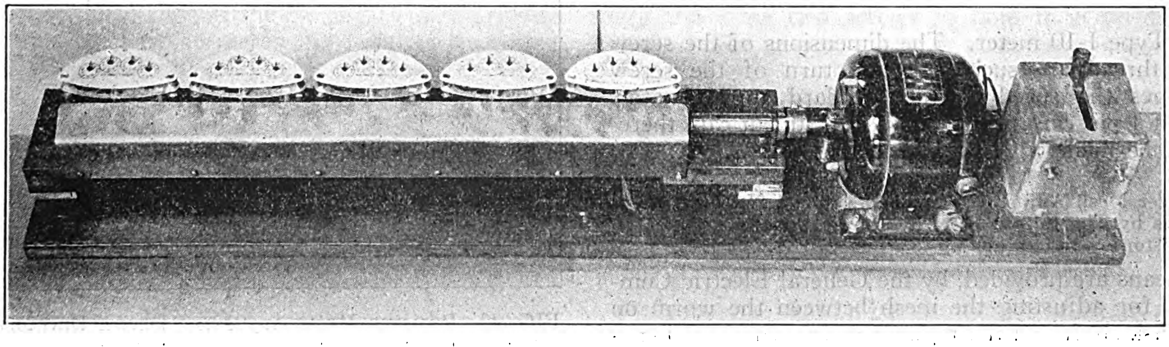

FIG. 39—DEVICE DEVELOPED BY THE NEW YORK EDISON COMPANY FOR CHECKING REGISTER RATIOS.

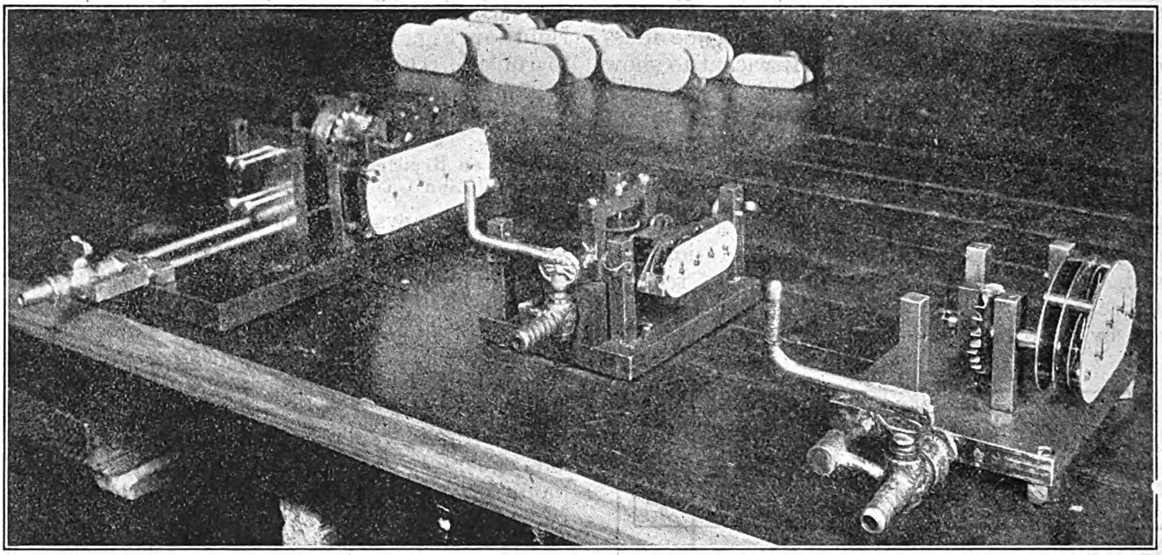

FIG. 40—AIR DRIVEN REGISTER CHECKING DEVICES DEVELOPED BY THE UNION GAS & ELECTRIC COMPANY.

are loosened on a standard, the magnets change their position relative to the disk, before any adjustment is made with the standard magnet adjusting screw. To eliminate this difficulty, a small bronze bracket is placed in front of the magnets, as shown in Fig. 41. A small iron screw is fed into the gap between the magnets in a manner similar to the full load adjustment of the General Electric Type I-10 meter. The dimensions of the screw and thread are such that one turn of the screw changes the speed of the standard approximately 0.1 of 1 per cent. Very close adjustment can, therefore, be made in a very short time.

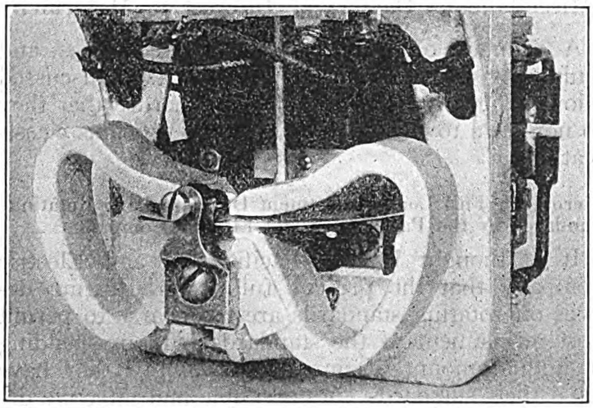

FIG. 41—MICROMETER FULL LOAD ADJUSTMENT DEVELOPED FOR ROTATING STANDARDS BY THE PACIFIC GAS & ELECTRIC COMPANY.

Register Mesh Adjusting Device Developed for Type D-7 Meters by The Edison Electric Illuminating Co. of Boston

Means are provided, by the General Electric Company for adjusting the mesh between the worm on the disk shaft and the register worm wheel of Types D-6, D-7 and I-14 watthour meters. This adjustment is properly made in the factory and should need no further attention as long as the original register is used. It is occasionally necessary to change registers, however, due to installation of contactors for demand meters, or of current transformers of different ratings. While the mesh of the new register may be correctly adjusted on the job, it is convenient to have the adjustment correctly made before the register leaves the meter laboratory.

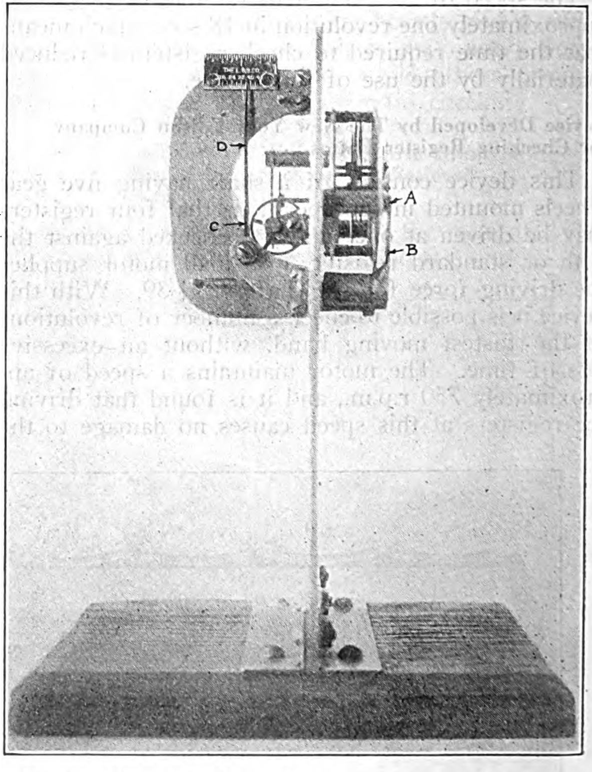

FIG. 42—REGISTER MESH ADJUSTING DEVICE DEVELOPED FOR TYPE D-7 WATTHOUR METERS, BY THE EDISON ELECTRIC ILLUMINATING COMPANY OF BOSTON.

A micrometer device has been designed to make possible the accurate setting of the worm wheels. The register is mounted on the device, as shown in Fig. 42. Two posts "A" fastened to the frame take the place of the usual mounting screws, and the register is held firmly by two clamps, "B." The worm wheel touches plate "C" on the pointer arm "D" and causes this latter to move in front of a scale. The arrangement is such that any movement of plate "C" is magnified several times at the tip of the pointer. The readings of the pointer for registers of meters used with instrument transformers and certain types of demand meters are kept on record. If a new register is required, it is adjusted to correspond with the measurement for the original register. By this means it is possible to allow the installer, who makes the change in the metering transformers, to change the registers at the same time.

Type IM-14 Pointer and Clutch Tension Checker Developed by The Detroit Edison Company

Fig. 43 shows the Type IM-14 Clutch Tension Checker built by the Detroit Edison Company for the use of meter testers in the field. The device is inclosed in a register box, the outside dimensions of which are 3½ in. x 3 in. x 5¼ in., and can be carried in the tester's kit along with his spare registers. The checker is fastened to the removable hinged cover of a register box, Fig. 44, and for convenience, it can be detached from the box when in use.

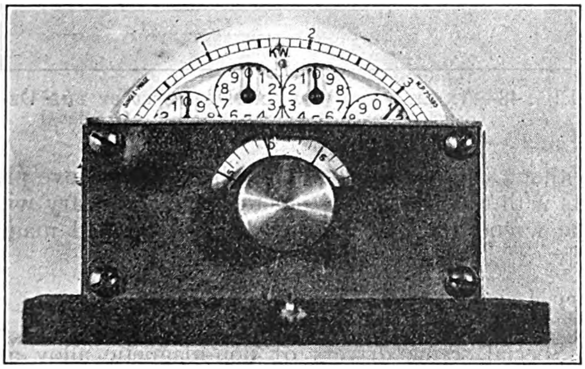

FIG. 43—TYPE IM-14 POINTER AND CLUTCH TENSION CHECKER DEVELOPED BY THE DETROIT EDISON COMPANY.

The checker works on the same general principle as most torque-balancers, with the exception that the jewels which support the moving element are stationary. The hair spring is the same as that used in the laboratory type checker manufactured by the General Electric Company. As it is made of phosphor bronze, it has no tendency to rust, as is the case with a steel spring. The balance wheel and sapphire jewels used in this device are taken from a time clock manufactured by the General Electric Company.

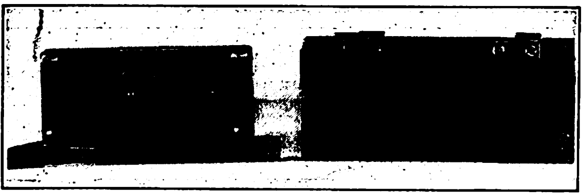

FIG. 44—BOX AND HINGED COVER FOR DEVICE SHOWN IN FIG. 43.

The rotating element is encased in a brass plate frame through which protrude the turning knob and pointer engager. The scale is visible through a semicircular window cut into the plate immediately above the turning knob. The scale has divisions on each side of the zero marking, one side ranging from 0 to 5 gram-millimeters for measuring pointer tension, and the other side from 0 to 25 gram-millimeters for measuring clutch tension. For pointer tension measurement, the pointer is moved to the right, and for clutch tension checking it is moved to the left. For this latter operation, the end of the pointer engages the clutch. By arranging the scale for the pointer and clutch on opposite sides of the zero marking, it is claimed that the chances of error in checking are reduced.

Contact-Making Device Developed for Westinghouse Type OA Registers by The Consolidated Gas, Electric Light and Power Co. of Baltimore

A simple contact-making device for Westinghouse Type OA registers has been devised and used by the Consolidated Gas, Electric Light and Power Company. It consists of a small brass plate, Fig. 45, on which is mounted an auxiliary shaft, gear star wheel, and contact brushes. To attach this device it is only necessary to remove two screws from the back plate of the register train, and to fasten the auxiliary device on the back of the register, using the same two screws to hold it in position, Fig. 46. The auxiliary gear is placed in mesh with the second gear of the register train. It is claimed that the simplicity of mounting makes it possible to install these devices on meters on the customers' premises.

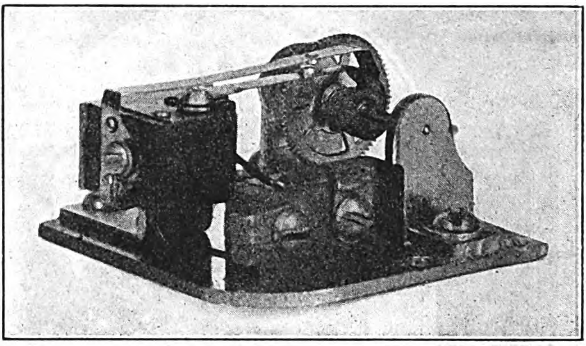

FIG. 45—CONTACT-MAKING DEVICE DEVELOPED FOR WESTINGHOUSE TYPE OA REGISTERS BY THE CONSOLIDATED GAS, ELECTRIC LIGHT & POWER COMPANY OF BALTIMORE.

Armature Testing Device Developed by The New York Edison Company

This device consists primarily of a voltmeter and a resistor, equivalent in value to the resistance of a combination shunt and resistor used in series with watthour meter armatures. The voltmeter is connected directly across two finger contacts which are

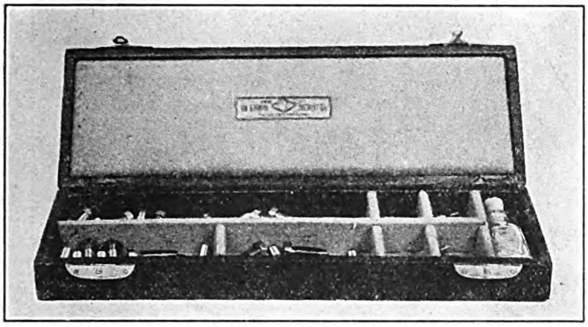

FIG. 50—INTERNAL VIEW OF JEWEL CASE SHOWN IN FIG. 49.

be carried. Special compartments are arranged for pivots, ball bearings, dial hands and oil bottle.

The lid fits securely down on the box and is held closed by two catches.

Meter Tester's Field Kit Used by The Union Gas and Electric Company

Fig. 51 shows a kit designed for the use of meter-men making tests in the field. The case is made of wood and covered with imitation leather. Elastic straps hold the tools in place. The ends of the case are tapered so that the end view of the kit, when closed, resembles a capital letter "A."

Portable Instrument Transformer Testing Sets Made by The Leeds & Northrup Company

The Leeds & Northrup Company makes portable current and potential transformer testing sets, as originally designed by Dr. Silsbee of the Bureau of Standards, Washington, D. C. These sets have been found very satisfactory by a number of public utility companies for testing instrument transformers used with watthour meters.

Fig. 52 shows such a set in use for checking the

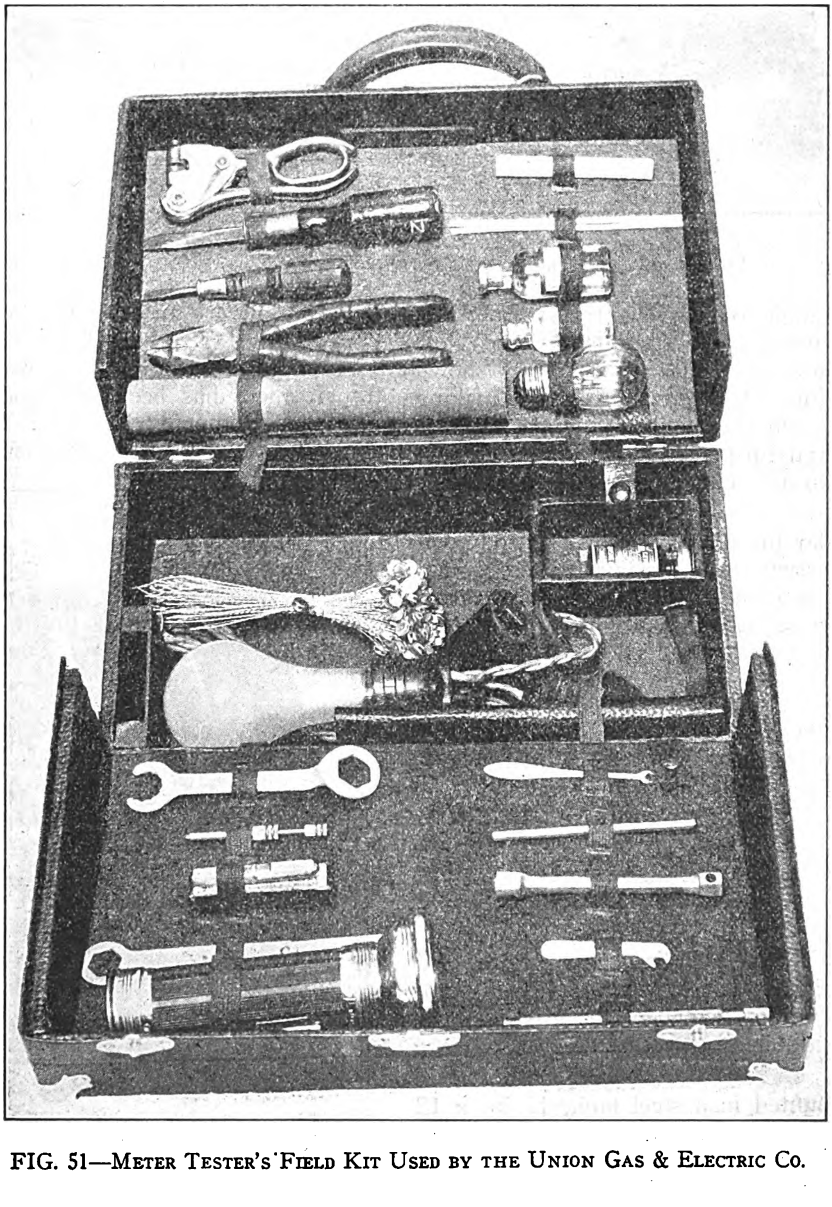

FIG. 51—METER TESTER'S FIELD KIT USED BY THE UNION GAS & ELECTRIC CO.

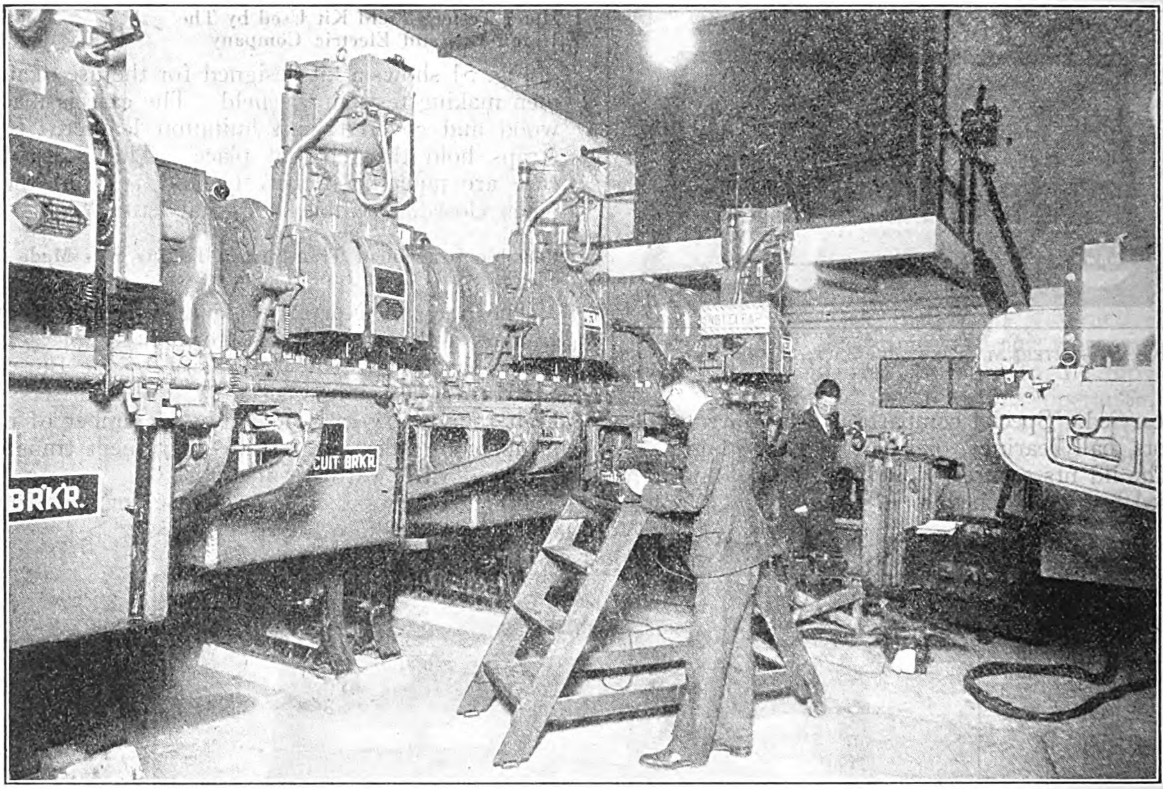

FIG. 52—PORTABLE INSTRUMENT TRANSFORMER TESTING SET MANUFACTURED BY THE LEEDS & NORTHRUP COMPANY IN USE IN AN A-C. DISTRIBUTING STATION OF THE NEW YORK EDISON COMPANY.

ratio and phase-angle of current transformers in one of the a-c. distributing stations of The New York Edison Company. The Silsbee set is shown in the center of Fig. 52, where the tester is making his observations. On the right of the same figure is shown a test transformer supplying large current at low voltage to the current transformer under test.

In this particular installation the use of the portable set became essential, as the current and potential transformers are imbedded in heavy insulating compound, and are permanently mounted in the iron-clad switch gear.

Multi-Range Potential Transformer Standard Manufactured by Otto A. Knopp

The standard potential transformer shown in Fig. 53 supersedes earlier types of a more limited range, reported in the 1924-1925 Report of the Meter Committee, N. E. L. A. The new transformer standard has the following voltage ranges: 110, 220, 440, 1100, 2200, 4400, 6600, 11,000 volts to 110 volts.

It is claimed that the windings are so designed that the same ratio and phase angle corrections apply to all ranges within a few hundredths of 1 per cent for ratio and one to two minutes for phase angle.

The unit is mounted in a steel tank, 12 in. x 12 in. x 10 in., which has a bakelite top. Handles are provided to facilitate transportation.

Adjustable Burden Made by The Leeds & Northrup Company for Testing Current Transformers

An adjustable burden for use in testing current transformers has been developed by the Leeds & Northrup Company, Fig. 54. This adjustable burden has a maximum rating of 50 volt-amperes at 60

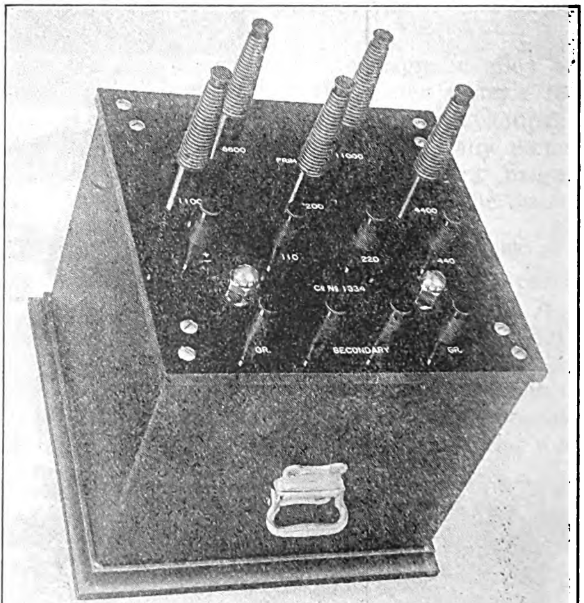

FIG 53—MULTI-RANGE POTENTIAL TRANSFORMER STANDARD MANUFACTURED BY OTTO A. KNOPP.

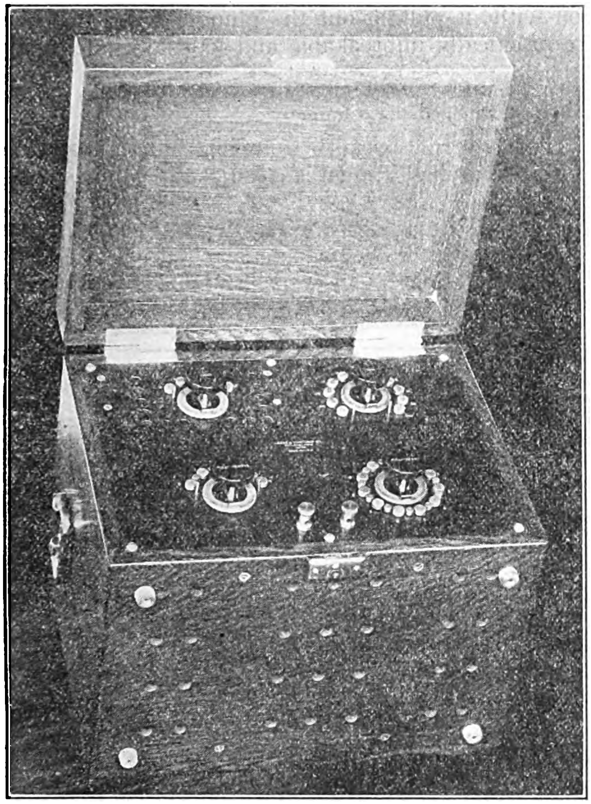

FIG. 54—Adjustable Burden Made by the Leeds & Northrup Company, for Testing Current Transformers.

cycles. The burden power factor can be varied between 100 per cent and 10 per cent. This latter value can be obtained using only the inductance portion of the device. The resistance section can be adjusted in steps of 0.04 ohm, while the inductance section can be adjusted in steps of 0.1 millihenry. The apparatus is designed to carry 5 amperes continuously, or 7.5 amperes for a short time.

This company has in the process of development a similar set of burdens for potential transformer testing, and also a portable device for measuring both current and potential transformer burdens.

Marking Current Transformers

The reading of current transformer nameplate ratios is very often necessary after the transformer has been placed in service. In some cases the transformers are so located that this becomes a rather difficult and dangerous task. To eliminate this difficulty, some companies find it advisable to mark the respective nameplate ratios on the transformers, with large numerals, legible at a considerable distance. Fig. 55 shows the practice of the Consolidated Gas, Electric Light and Power Company of Baltimore.

Other companies, such as The New York Edison Company, find it more advisable to stencil the manufacturer's serial number rather than the nameplate ratio on each transformer. The complete nameplate data are kept on record in the office. Therefore, all the necessary data for any transformer becomes available once its serial number is determined.

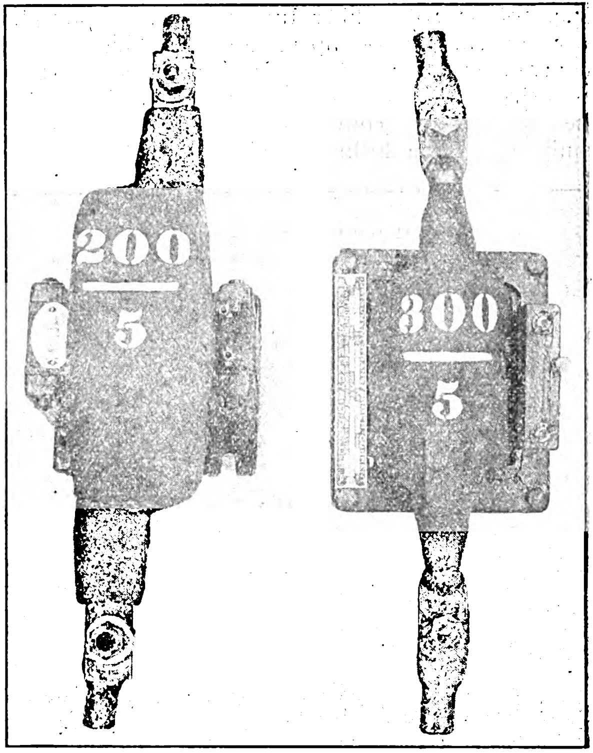

FIG. 55—A Method of Marking Current Transformers with Large Numerals.

Adapter Test Clip Developed for Test Lead Plugs by The Detroit Edison Company

The Detroit Edison Company has developed a device consisting of a test clip, to which is attached a plug receptacle, so that it can be forced over the usual test lead plug. The receptacle holds the plug securely with a friction fit, and a test connection can be easily made with the test clip. This device, Fig. 56, is claimed to be valuable when using a series loop while working on test boxes. With two additional test clips the series loop can be safely held in place.

Saf-T-Klips Made by The Superior Switchboard and Devices Company

Saf-T-Klips as manufactured by the Superior Switchboard and Devices Company constitute an improvement in test clips for meter work. The Saf-T-

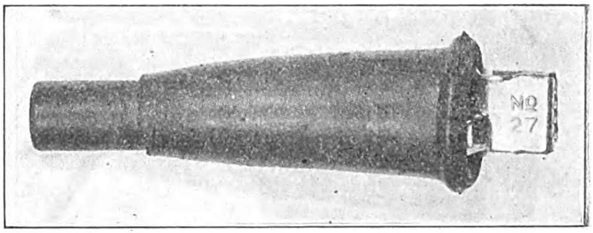

FIG. 56—Adapter Test Clip Developed for Test Lead Plugs, by the Detroit Edison Company.

Klip consists of a fiber tube inclosing a phosphor bronze spring of 60-ampere capacity. This spring is so arranged that, when the plunger or rod is pressed into the tube, the contacts located at the end of the spring are compressed. The contacts are equipped with a locking device especially designed for this company's "1000 Line" Test Switches, described elsewhere in this report. Fig 57 shows the Saf-T-Klip in the open and closed positions. Fig. 58 shows the Saf-T-Klips in use on a Superior test switch.

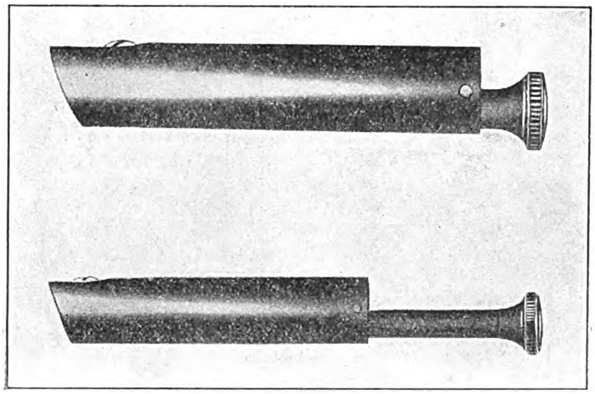

FIG. 57—SAF-T-KLIPS MADE BY THE SUPERIOR SWITCHBOARD COMPANY.

The manufacturer claims that it is impossible to pull off the Saf-T-Klip after it is placed in position without pulling out the plunger; also that they are practically unbreakable and will last indefinitely.

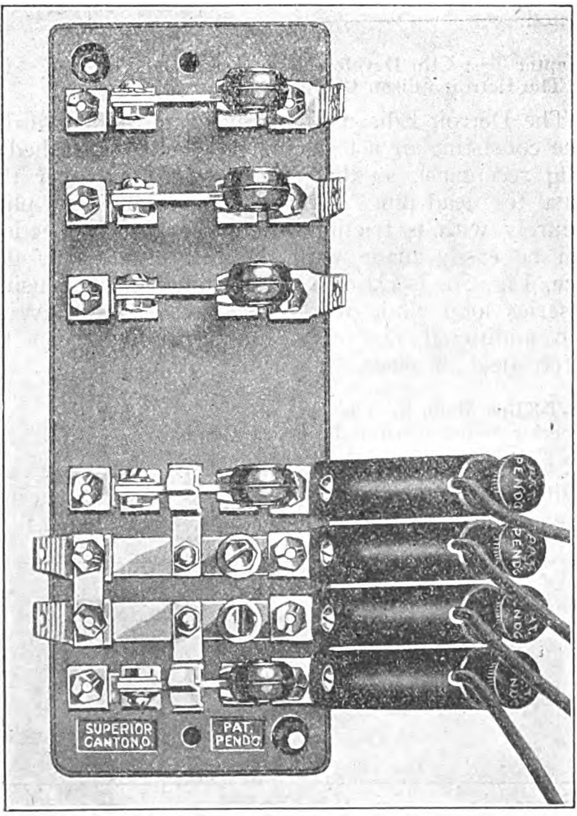

FIG. 58—SAF-T-KLIPS MOUNTED IN POSITION.

Tesco Type ES-7 and ES-10 Test Switches Made by The Eastern Specialty Company

The Eastern Specialty Company announces a line of test switches known as the Tesco Types ES-7 and ES-10. The Type ES-7 test switch, Fig. 59, is designed especially for use with two and three-phase, three-wire, two-element meters. The Type ES-10 test switch, shown with cover removed in Fig. 60, is designed for use with three-phase, four-wire, three-element meters. They are furnished in either front or rear connected types, with and without glass covers. The bases are made of molded material, and the switch blades are of special cold-rolled copper. Auxiliary blades are attached to one blade of these switches to short-circuit the secondary circuits of current transformers before breaking the circuit through the main blades.

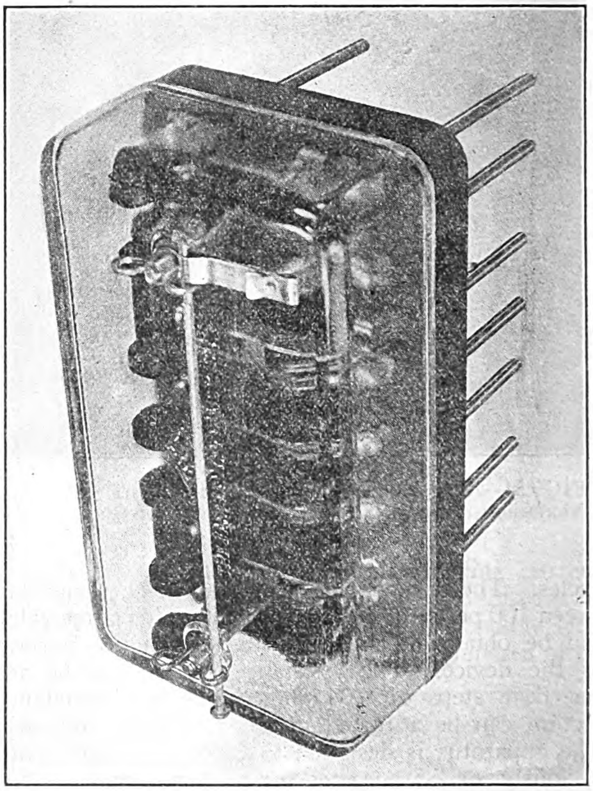

FIG. 59—TESCO TYPE ES-7 TEST SWITCH MADE BY THE EASTERN SPECIALTY COMPANY.

Type SJ Test Block Made by The States Company

One of the features of the new States Company Type SJ Test Block is the shunted jack principle used in the design of the current units. The shunted jack scheme eliminates the possibility of forgetfulness on the part of the tester to tighten screws or other arrangements, sometimes used to clamp jack contacts in switch type test blocks. Further, the jack contacts are not depended upon to

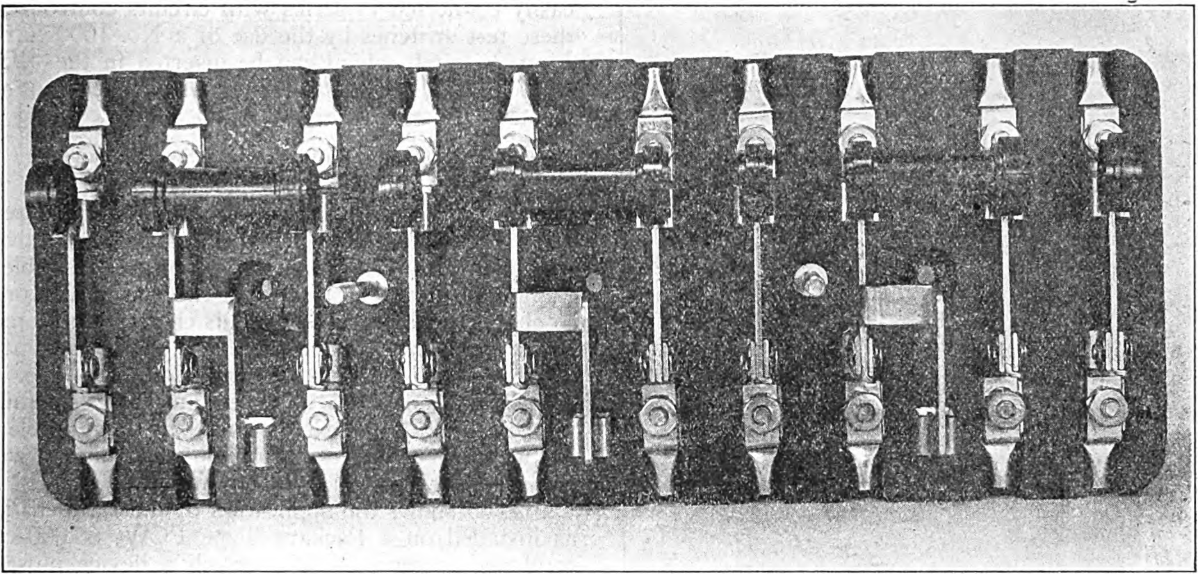

FIG. 60—TESCO TYPE ES-10 TEST SWITCH MADE BY THE EASTERN SPECIALTY COMPANY.

carry current. Reference to Fig. 61 shows that a knife switch shunts the jack contacts. This switch is open only when the jack is in use. The cover of the block may be removed without disturbing connections. It cannot be replaced unless all of the switch blades are in the "closed" position. The current units of the block are so arranged that it is impossible to open-circuit current transformer secondaries.

The test plugs, which may be supplied with the blocks, are easily inserted at right angles to the block. A specially formed test clip strip insures good test clip connection, and eliminates the possibility of a test clip slipping off.

All switch and jack jaws are made of special high

spring stock, that is tempered to give a lasting spring tension. All nuts on the blocks have slotted heads. An ordinary screw driver is the only tool necessary to make connections. The base is molded and all metal parts are treated with corrosion-resisting material. The seven-pole block base is 7½ in. x 3¾ in., as shown in Fig. 62.

"1000-Line" Meter Test Switches Made by The Superior Switchboard and Devices Company

The Superior Switchboard and Devices Company has recently put on the market 60-ampere test switches known as the "1000-Line" Superior Meter Test Switches. The unit known as the Cat. No. 1040 test switch is shown in Fig. 63. Ammeters can be easily connected in series with circuits controlled by these test switches by the use of a No. 1000 Saf-T-Plug, Fig. 64, which can be inserted in the "1000-Line" jack, built into one leg of each current element.

Current Transformer Ratio Changer Switch Made by the Packard Electric Company

Due to the variable load conditions encountered when measuring the exchange of power between interconnected systems, it is sometimes desirable to change the current transformer ratio, at will, in order to obtain higher accuracy. This change can be readily accomplished by the use of a device manufactured by the Packard Electric Company, Fig. 65. This device may also be used in cases of straight industrial load metering, where it is desirable to change the current transformer ratio quickly without undue trouble and power shutdown.

Fig. 66 shows the application of the ratio changer as installed on a Packard Type PCW, 66,000-volt, combined metering outfit. Such a device must be

FIG. 65—CONSTRUCTION DETAIL OF CURRENT TRANSFORMER RATIO CHANGER SWITCH MADE BY THE PACKARD ELECTRIC COMPANY.

installed in a manner that only authorized employees can operate it, inasmuch as the watthour meter readings must be taken each time the ratio is changed.

The Quadraphaser Made by The States Company

For metering reactive volt-ampere-hours, it is necessary to supply to the potential circuit of the meter a voltage displaced 90 deg. from the voltage used for metering watthours. The Quadraphaser is a device which combines the necessary transformers to produce this voltage, along with a four-pole Type DT angle blade switch.

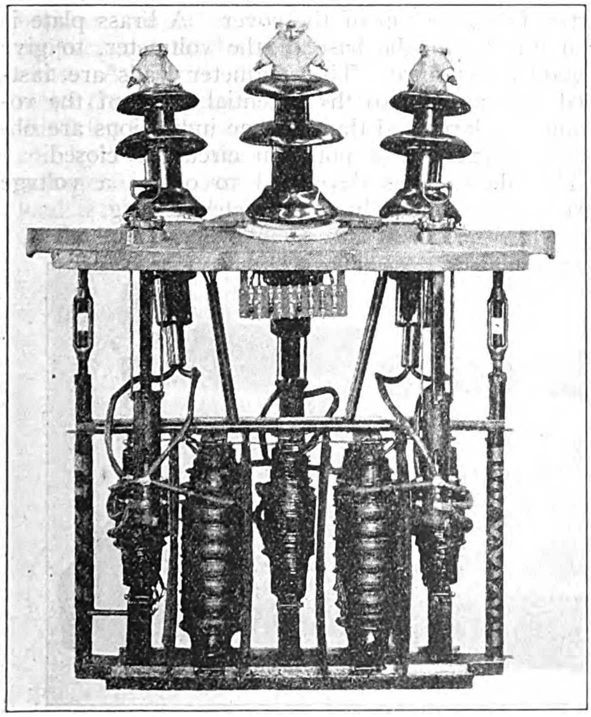

FIG. 66—RATIO CHANGER SWITCH INSTALLED ON A 66,000-VOLT METERING OUTFIT.

The manufacturer states that the transformers are especially designed and have ample capacity for the particular service of measuring the reactive component. The four-pole switch serves to disconnect the transformers and to supply normal voltage to the meter for testing it as a watthour meter. The Quadraphaser is normally supplied with a cover made of bakelite with metal ends. It is impossible to place the cover of the Quadraphaser on the base unless the switch is in the "run" position. This eliminates the possibility of leaving the meter registering kw-hr. rather than reactive kv-a-hr. after the test.

The device, Fig. 67, is 12 in. long, 4 in. wide and 3½ in. high. Fig. 68 shows the wiring diagram of an installation where a Quadraphaser is used.

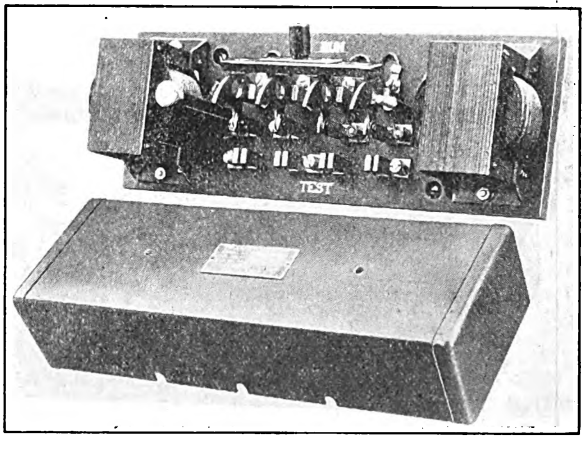

FIG. 67—THE QUADRAPHASER MADE BY THE STATES COMPANY.

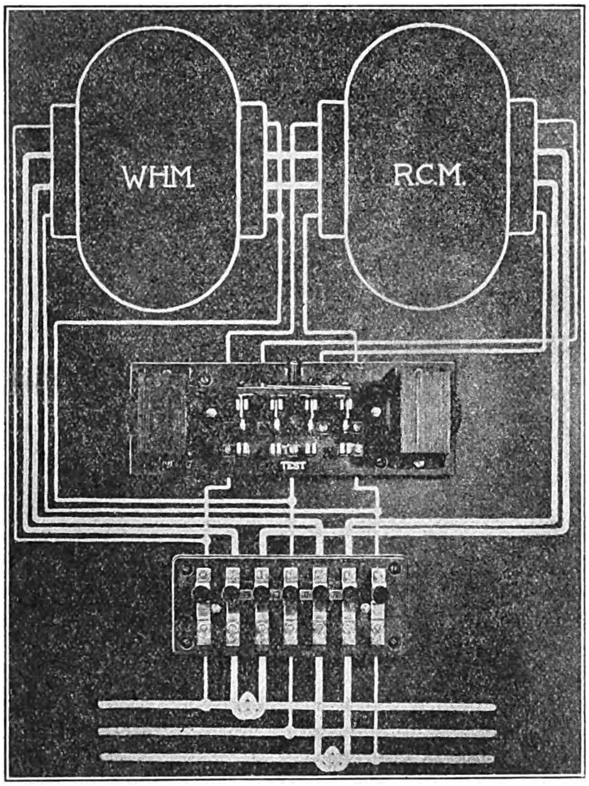

FIG. 68—CONNECTION DIAGRAM FOR USE WITH THE DEVICE SHOWN IN FIG. 67.

Reactiformers Made by The Superior Switchboard and Devices Company

Another device of a similar nature and designed for the purpose of combining phasing transformers with a meter testing device is manufactured by the Superior Switchboard and Devices Company.

The Reactiformer shown in Fig. 69 is designed for three-phase, three-wire service, while the one shown in Fig. 70 is designed for three-phase, four-wire service. The manufacturer states that both the initial cost and the cost of operation are considerably less than the old method of using a separate test switch and auto transformer.

Torque Checking Device Developed for Warren Motors by The Edison Electric Illuminating Company of Boston

When Warren motors are used in heavy duty instruments, such as graphic demand meters, the gears become worn or other defects develop after a few years of service, and the motor is liable to fail. To detect faulty motors in advance of actual failure, a simple torque testing device, Fig. 71, has been developed and used with satisfactory results by the Edison Electric Illuminating Company of Boston. It will be noted from Fig. 71 that the device consists of an arbor "A," on one end of which is mounted a cup "B" which fits over the pinion and shaft of the Warren motor. A pointer is mounted on the other end of the arbor.

A helical spring, consisting of ten turns of 0.017-in. diameter piano wire is attached to arbor "A," as indicated in Fig. 71. A small pin in the cup engages the pinion of the motor under test.

A motor is considered safe to use if, at rated voltage, it has sufficient torque to turn the pointer one complete revolution. All motors with less torque are returned to the manufacturer for repairs.

Combined Rotating Standard and Voltmeter Assembled by The Buffalo General Electric Company

The Buffalo General Electric Company has equipped all its rotating standards with a modified Type TA, Roller Smith voltmeter, Fig. 72. In order to obtain sufficient room to accommodate the depth of the voltmeter, a 2⅝-in. hole is bored in the cover of the standard, and the voltmeter is inserted from the top of the cover. A brass plate is then fitted over the base of the voltmeter, to give a good appearance. The voltmeter leads are fastened permanently to the potential posts of the rotating standard, and thus voltage indications are obtained whenever the potential circuit is closed.

This device was developed to obtain a voltage survey simultaneously with meter testing.

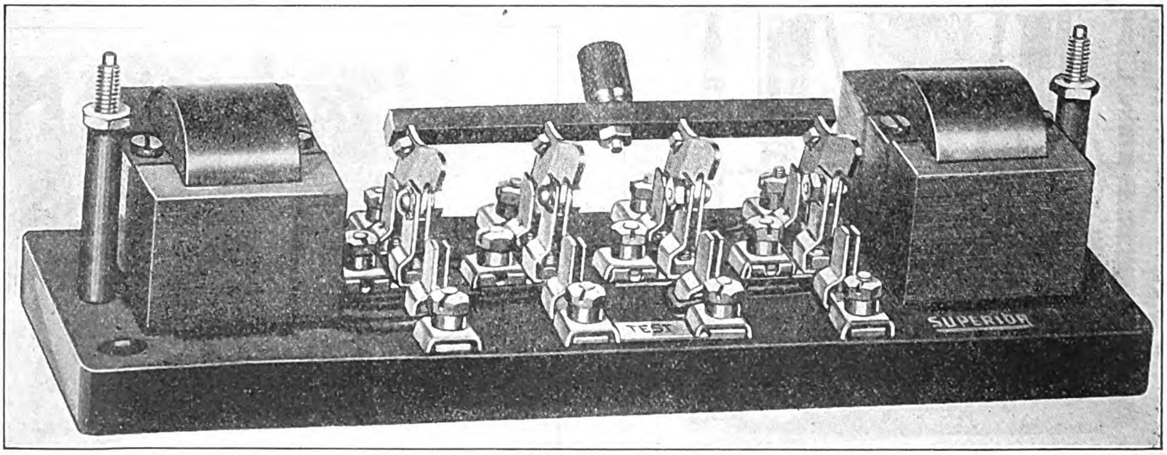

FIG. 69—REACTIFORMER DESIGNED FOR 3-PHASE, 3-WIRE SERVICE MADE BY THE SUPERIOR SWITCHBOARD & DEVICES COMPANY.

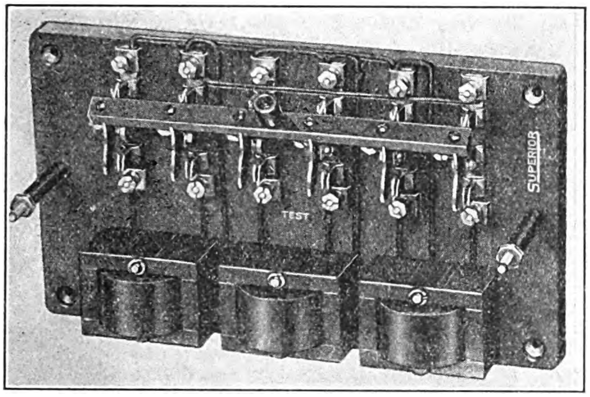

FIG. 70—REACTIFORMER DESIGNED FOR 3-PHASE, 4-WIRE SERVICE MADE BY THE SUPERIOR SWITCHBOARD & DEVICES COMPANY.

Alternating-Current Voltmeter Testing Device Developed by The Buffalo General Electric Company

The Buffalo General Electric Company has developed a device, shown schematically in Fig. 73, for checking alternating-current voltmeters. It consists of a transformer of three windings on a conventional "H" core. The winding on one outside leg serves as the primary, which can be excited from any convenient 115-volt source of a given frequency, such as a potential transformer. The winding on the center leg serves as a secondary or source of potential for the instruments under test. It is provided with several taps to cover the range of voltage desired. The third winding is on the remaining leg of the core, and is connected to a variable resistor.

The device functions in the following manner: With no load on either of the two secondary windings, the flux set up by the primary coil is divided between the other two legs of the core, inversely proportional to the reluctance of the magnetic circuits. As load is placed on the center coil, the flux in its core decreases and accordingly the flux in the third leg increases. As load is placed on the third coil by varying the resistance in series with it, the voltage of the second coil is increased. Hence, as load is increased on the third winding, the voltage on the instrument under test is increased. The rheostat in the third coil, together with the various taps in the center coil, enables the operator to obtain any voltage value quickly and smoothly within the range of the device. The whole device is mounted in a carrying case similar in size and weight to a rotating standard.

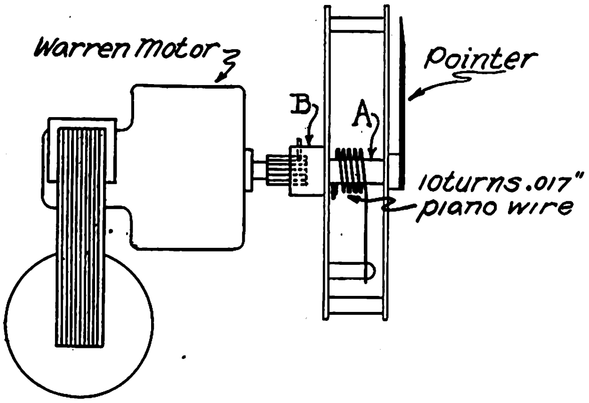

FIG. 71—TORQUE CHECKING DEVICE DEVELOPED FOR WARREN MOTORS BY THE EDISON ELECTRIC ILLUMINATING COMPANY OF BOSTON.

Equipment Assembled by The New York Edison Co. for Testing Automatic Sub-Station Line Relays

For testing the sensitivity of "Line Relays" used in automatic sub-stations equipped with the General Electric Company distributor type of supervisory system, the device shown in Fig. 74 has been designed and constructed by The New York Edison Company.

The Line Relay, "R" in Fig. 74, is inserted into the jack located at the upper left hand corner of the device. A test supply of 48 volts is connected to the binding posts shown at the upper right hand

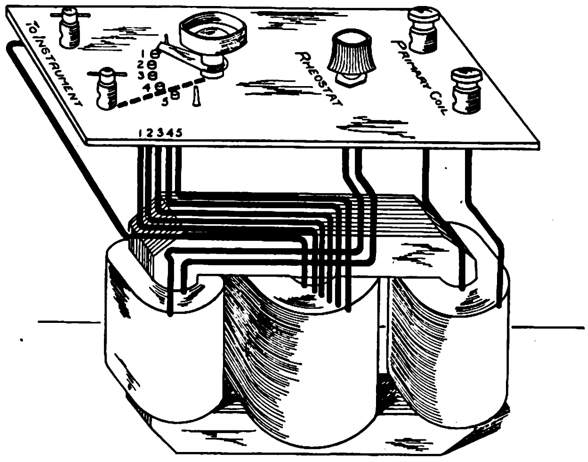

FIG. 73—ALTERNATING-CURRENT VOLTMETER TESTING DEVICE DEVELOPED BY THE BUFFALO GENERAL ELECTRIC COMPANY.

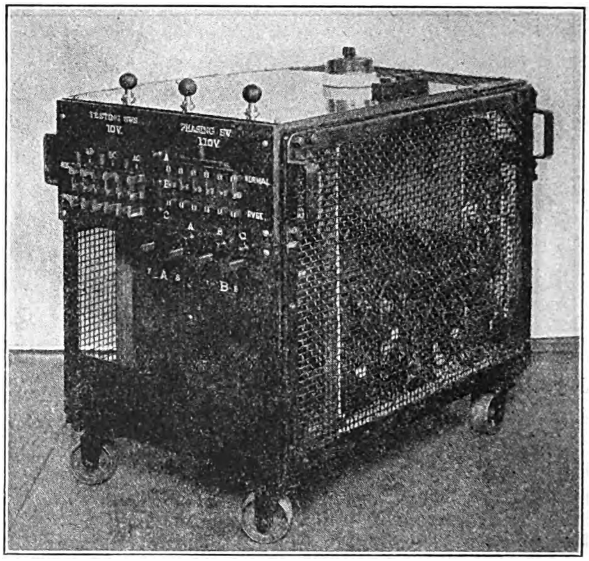

FIG. 75—THREE-PHASE TEST SET USED BY THE UNION GAS & ELECTRIC COMPANY FOR TESTING TRUCK SWITCH RELAYS.

corner of the device; the rheostat on the left, below the relay jack, controls the current; the flush-top double pole double throw reversing switches on the right permit the necessary switching; and the snap switch, below the right hand binding post controls the test supply. The milli-ammeter, connected to the device by a plug and jack, serves to measure the test current, which is 70 to 80 milli-amperes.

This device has been found very satisfactory for testing this type of relay, as it eliminates all possibility of wrong test connection and reduces the testing time to a minimum.

Three-Phase Test Set Used by the Union Gas and Electric Company for Testing Truck Switch Relays

This test set, Fig. 75 and 76, is designed primarily to make an overall test on relays and transformers installed on truck switches where the relays and current transformers are mounted on the movable member of the truck. The test is made by applying three-phase current directly to the main contacts of the truck switch and noting the operation of the relays.

Where truck switches are assembled and wired in the shop before delivery to the field, a final check can be made in a few minutes using this device. If a test in the field is desired, the set can readily be transported to the desired location.

The following tests can be made with this device:

Determination of ratio and polarity of current transformers. .

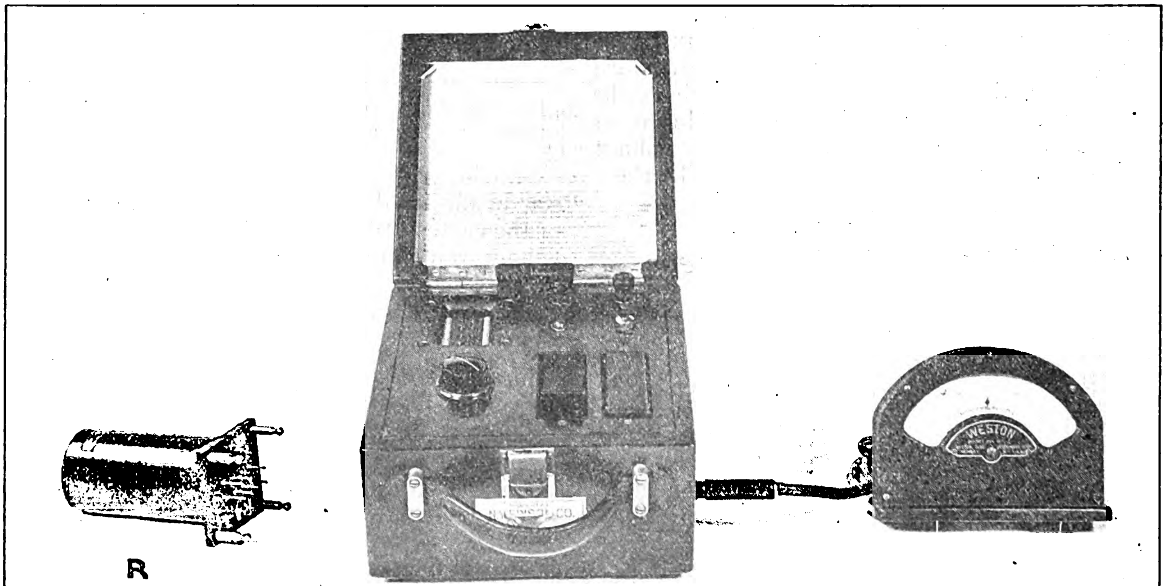

FIG. 74—EQUIPMENT ASSEMBLED BY THE NEW YORK EDISON COMPANY FOR TESTING AUTOMATIC SUBSTATION LINE RELAYS.

- Determination of ratio and polarity of potential transformers (when mounted on movable member).
- Determination of operation of over-current relays.
- Determination of the wiring condition of over-current relays.
- Determination of operation of directional relays.
- Determination of the wiring condition of directional relays.
- Determination of phase relations between feeder and customer's bus.
- Location of loose connections.

The test set consists primarily of three single-phase transformers, each having three secondary windings. The main secondary winding is designed to supply 1200 amperes at 5 volts for 10 minutes. One of the auxiliary secondary windings is designed to supply 10 volts for exciting the potential element of a power-directional relay, while the other auxiliary winding is designed to supply 115 volts for testing directional relays, and for determining phase relation between the customer's bus and the potential transformers mounted on the stationary member of the truck switch, or on another switch. The primary windings can be connected to 230 or 460-volt circuits.

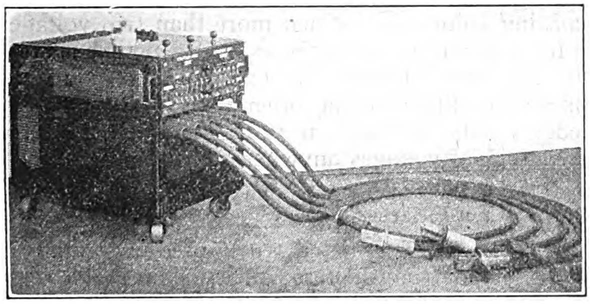

FIG. 76—DEVICE SHOWN IN FIG. 75 WITH SECONDARY CABLES ATTACHED.

Each transformer is excited through a double-pole switch and is wired so that, with all switches closed, the primary windings are connected in delta. Each transformer can also be energized separately to determine if each relay is connected to the proper phase.

The 5-volt winding of each transformer is supplied with 300,000-circular mil flexible leads and contactors which fit into the truck switch contacts. A grid resistor is connected in series with each lead, to reduce the current to approximately 600 amperes, for the purpose of determining the operation of the relays at the lower current values. A short strap is provided to short-circuit this resistor.

The ten-volt auxiliary windings are connected to a six-pole reversing switch to make possible the reversal of phase rotation. These windings are connected in delta by the six-pole reversing switch, and then to three terminals. The terminals are connected to the relays through the auxiliary contactors on the truck switch. The 115-volt auxiliary windings are similarly connected to three terminals through a six-pole reversing switch.

When potential transformers are mounted on the movable member of the truck switch, the primary windings of the potential transformers are connected directly to a 230 or 460-volt supply by means of a three-pole snap switch mounted on the test set. As the truck switches for which this test set is designed are used on 7800 and 13,200-volt feeders, sufficient voltage is applied to the directional relays in this manner.

The current in the main windings is measured by means of small through-type current transformers, which are slipped on one lead from each transformer. When instruments are required for use with the set, the portable type is used for greater accuracy and to prevent damage in transportation.

The method of connection has been determined and marked so that, when the test set is connected to a truck switch and current applied, the action is the same as if a fault had been applied to the feeder in service. In this manner, three-phase and single-phase faults can be simulated. By means of the potential reversing switches, the action of the directional relays can be tested under conditions which represent a fault on either of the two feeders supplying a given loop installation.

The utility that designed this set advises that by its use any errors of operation that are present, especially such errors that occur only when all the circuits of the truck switch are energized, can be detected. Tests with this device are made to supplement a detailed wiring check of relays.

Resistor Assembled by the New York Edison Co. for Testing Power-Directional Relays

A resistor has been developed by The New York Edison Company for testing power-directional relays at low voltage. This unit, shown in Fig. 77, eliminates the necessity of using a low reading voltmeter, as at 8 amperes it gives a voltage drop of 3 volts. Eight amperes and 3 volts are test values at which the relay must operate in 0.25 second to pass the low voltage test.

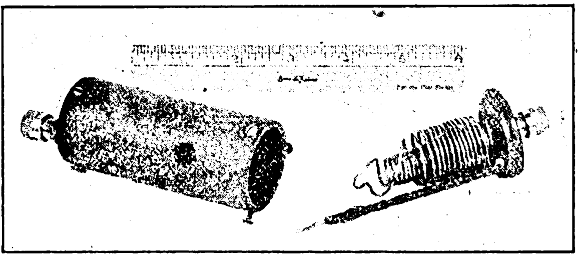

FIG. 77—RESISTOR ASSEMBLED BY THE NEW YORK EDISON COMPANY FOR TESTING POWER-DIRECTIONAL RELAYS.

The resistor is inserted in the current circuit of the relay, and the current is adjusted to 8 amperes. The voltage appearing at the terminals of the resistor is applied to the potential coil of the relay, with the assurance that its value is 3.0 volts and it is in phase with the current.

The resistor is wound non-inductively of manganin wire, which also eliminates resistance changes with temperature.

Three-Wire Test Lamps

Meter testers of the Brooklyn Edison Company are supplied with three-wire test lamps, for use when working on sections of the system which have been changed over from delta services, metered with 120-240 volt, three-wire, single-phase meters, to one of two legs and neutral of a four-wire, three-phase system giving 120-208 volt service. These test lamps consist of two lamps connected in series, and the connection between them is brought out so that voltage to ground can be readily checked. The middle lead is made shorter in order to identify it, and thus prevent placing a single lamp across 208 or 240 volts.

If the two outside leads are placed across a circuit and the lights do not burn at full brilliancy, the middle lead is then grounded. If the lights come up to full brilliancy, the circuit is identified as a 120-208-volt circuit. If the circuit is a 120-240-volt, single-phase circuit, the lights will remain brilliant with or without the neutral wire grounded.

This method of connecting test lamps is used quite generally by other utilities for identifying various types of services.

A Method of Recording Two or More Voltages on One Chart Used by The Edison Electric Illuminating Co. of Boston

It is sometimes desirable to obtain a record of two or more voltages on one chart, as for example, the voltages of the two sides of a three-wire, single-phase circuit or the individual phases of a polyphase circuit. This may be done by means of a switching device that will alternately connect the voltmeter across the different voltages to be measured. Fig. 78 schematically illustrates a transfer or commutating switch of this kind for obtaining the voltages of the two sides of a three-wire, single-phase circuit. Fig 80 shows a chart obtained by the use of this device. It will be noted that the time intervals are not equal, the voltmeter being connected to one side for a longer time interval than to the other side. This is done so that the voltage records may be readily identified.

When the voltmeter connection is transferred from one side to the other, the circuit is broken for a very short interval, and the stylus or pen arm tends to return to the zero point of the chart. The line thus made on the chart further aids in distinguishing between the records of the two voltages. The transfer switch may be a separate clock-driven device, as shown in Fig. 78, or may be a part of the recording voltmeter. When more than two voltages are to be recorded, as in the case of a polyphase circuit, the time interval for one voltage should be longer than that for the others. Knowing the sequence of the voltages, it is then easy to identify the individual voltages anywhere on the chart.

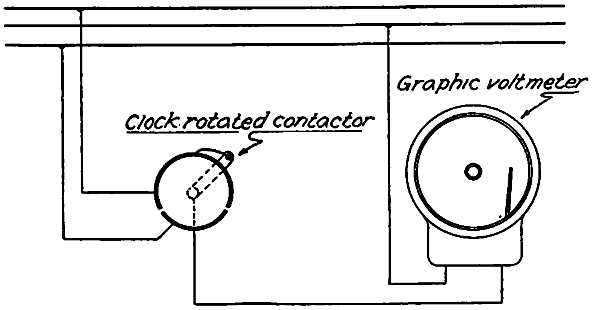

FIG. 78—A METHOD USED BY THE EDISON ELECTRIC ILLUMINATING COMPANY OF BOSTON FOR RECORDING TWO OR MORE VOLTAGES ON ONE CHART.

Meter Truck Used in the Laboratory of The Union Gas and Electric Company

Fig. 79 shows a meter truck used to transport meters to and from the test panels in the Inside Test Department of the Union Gas and Electric Company. These trucks are substantially built of oak and equipped with rubber-tired steel wheels. Each truck has a capacity of eighty meters. A bar across the end facilitates handling.

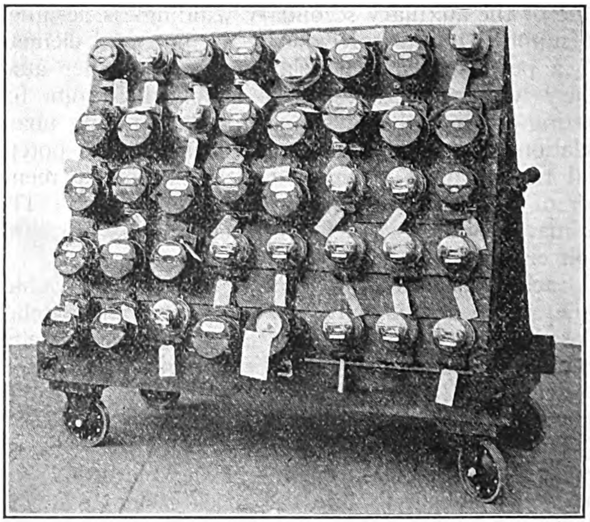

FIG. 79—METER TRUCK USED IN THE LABORATORY OF THE UNION GAS & ELECTRIC COMPANY.

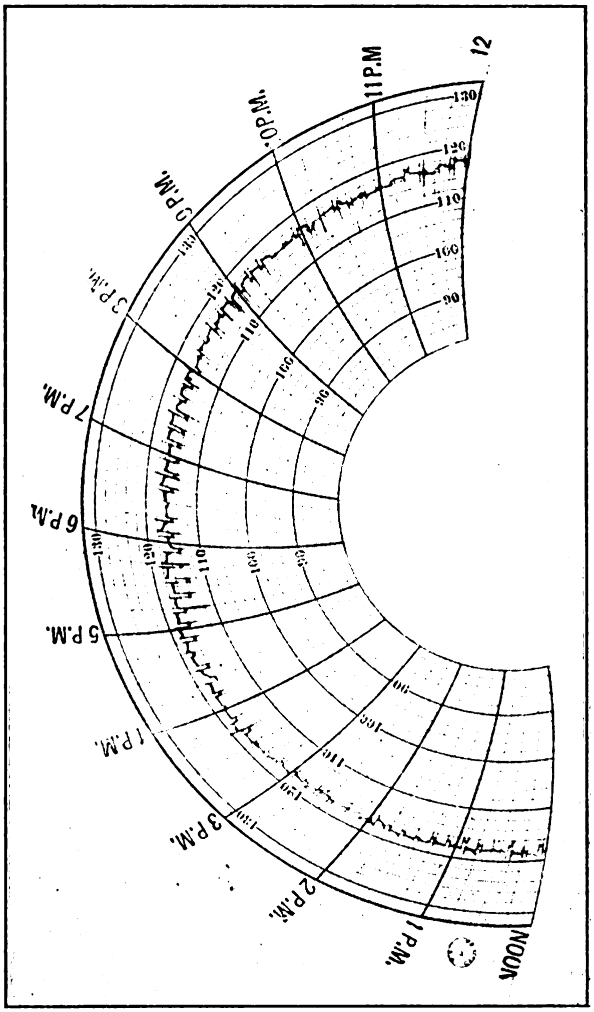

FIG. 80—CHART SHOWING VOLTAGE RECORDS MADE BY THE DEVICE SHOWN IN FIG. 78.

PRACTICAL USES OF STEEL AND CONCRETE POLES

STEEL POLES

A steel pole, as distinguished from a steel tower; is defined as a narrow beam structure, which may be located in approximately the same space as a wood or concrete pole.

The following report presents some of the general considerations relative to the use of steel poles followed by a summary of replies to a questionnaire on their use by companies in this country.

The general advantages of steel poles over wood poles may be summarized as follows: Longer life, greater strength, lower maintenance cost and smaller depreciation charges. The disadvantages are: Higher initial cost, greater hazard for linemen at work, and in the case of fabricated structures, greater ease with which they may be climbed by an unauthorized person.

However, there is no hard and fast rule which dictates the use of steel poles over wood poles or any other structure. Each line must be judged on its own merits, and a careful study made of all the factors involved before a choice can be made.

The conditions under which steel poles are frequently used are as follows:

(a) When the right of way is narrow or otherwise restricted, such as on city streets, along highways, along railroads or on private property.

(b) At angles in the line where conditions will not permit the use of guys, then self-sustaining steel poles may be used.

(c) Where the number of circuits, size of conductors and length of span require strength which it is impracticable to secure by the use of wood poles.

(d) Where a study of the economies of the line show that the larger capital cost and heavier fixed charges of a steel pole line are more than offset by its lower maintenance and depreciation charges.

(e) Where the importance of the line or the available right-of-way is insufficient for a steel tower line, but is suitable for a steel pole line.

(f) Where the matter of appearance is of sufficient importance to warrant the extra cost of steel poles.

Design Specifications

Specifications pertaining to design should cover fully the following points:

Voltage of line.
Maximum length of span and ruling span.
Size of wire. material and characteristics.
Assumed thickness of ice and velocity of wind.
Number of circuits and arrangement.
Number and size of ground wires, if any.
Distance between phases.
Distance between circuits.
Length of insulator string, including hardware
Lateral swing of insulator string.
Minimum clearance to steel of live parts.
Minimum clearance of conductors over ground. over highways, to adjacent structures, etc.
Maximum tension in conductors.
Amount of tension reduction in conductors to allow for swing of insulators into catenary, under condition of broken conductor.
Number of broken conductors.
Maximum angle in line.
Loading combinations.
Allowable unit stress—tension, compression, shear and bearing.
Slenderness ratio of compression members.
Minimum size of shapes and bars allowed.
Minimum thickness of metal allowed.
Size of bolts and bolt holes.

The following matters of detail design should also be considered in the specifications:

Accessibility of all parts for inspection; avoidance of pockets or depressions which would hold water; avoidance of eccentricity in joints and connections, or a proper provision for eccentric stresses where eccentricity is unavoidable; chamfering the back of the inside angle in lap splices; inclination of lattice bars and other latticing details.

Such details as type of ground wire connection, insulator, support, size and location of ladder bolts, if any, and type of foundation or footing, should also be given consideration in the specifications.

Fabrication

The quality of fabrication is of utmost importance, not only that the resulting line may be first class, but also that erection difficulties and costs may be reduced to a minimum.

Specifications should usually include the following requirements:

Workmanship to be in accordance with first-class practice.
All members to be carefully straightened at shop before being shipped.
All members to be properly marked for identification in the field, and such marks shall not later be rendered illegible by galvanizing or careless handling.
Small parts to be securely wired into bundles, and all nuts, bolts, etc., to be boxed and marked.
One of each type of pole to be completely assembled at shop before any shipment is made.
If material is galvanized, it should be done as

Publication No. 289-6, Serial Report, Overhead Systems Committee.

the last process of fabrication.

Careful handling and inspection will be necessary in order to avoid shipment of members warped by galvanizing process.

Minimum diameter of bolts to be specified. If possible, all bolts to be of same diameter throughout structure in order to facilitate erection.

Threads of bolts to be outside of members connected, i.e., bearing to be on full section of bolt.

Preferable that not more than three members be held by one bolt.

Punching to be done accurately, but an occasional slight inaccuracy in the matching of holes that may be corrected with a reamer will be tolerated.

Inaccurate punching, which necessitates drifting during erection, not to be accepted.

Foundations

Steel pole footings can be designed either for earth back-fill or for concrete, depending upon the character of the line and other considerations.

The question of adequate foundation design is very important. The maximum load on the poles and the resulting reaction in the soil, together with the soil condition, should be carefully analyzed.

When set in earth, channels and plates are bolted to the main footing members in order to distribute the load over the soil. If set in concrete, then the concrete block distributes the load.

Summary to Replies to Questionnaire

The information printed below is the result of answers to a questionnaire which was sent to all principal utilities of the country. Forty-six replies to the questionnaire were received. Six of these replies indicated the use of steel tubular poles for trolley and street lighting and were, therefore, excluded, leaving forty replies which have been summarized below.

Question: Describe uses of steel poles, giving span, size and number of conductors and voltages of lines supported.

	Transmission	*Distribution*
Number of users reported	24	16
Spans used	300 ft. to 440 ft. 600 ft. to 800 ft. in two special cases.	90 ft. to 180 ft.
Size of conductors	Up to 4/0 copper	Up to 1,000,000 C.M.
Number of conductors	From 3 to 6	Up to 10
Voltage	Up to 120 kv. 33 to 66 kv. most common.	

From the above table it is obvious that steel poles have a wide variety of uses for practically all types of transmission and distribution service. The most common use is for transmission lines of 300 to 440 ft. spans, the poles carrying three or six conductors up to 4/0 in size and at a voltage of between 33 and 66 kv. Two replies indicated spans of 600 to 800 ft. using six conductors at 110 or 120 kv. Distribution lines on steel poles are generally in city streets and consist of secondary lines in conjunction with trolley lines. Six replies indicated distribution lines up to 4400 volts are placed on steel poles.

Question: What is the width of right-of-way and what clearance to ground, adjacent buildings and other structures do you provide for?

Only eleven replies give data on right-of-way. In these cases the width of the right-of-way varies between 10 and 100 ft., the most common width being 30 ft. The balance of the replies indicate that steel poles were placed on streets or highways or on private property with easements. This indicates that steel poles are suitable where right-of-way is narrow either by reason of circumstances or because of cost. Generally the experience of utilities seems to be that a right-of-way for steel poles is much easier to obtain than for towers, and is usually less expensive.

Clearances in general conform with the National Electrical Safety Code.

Question: What crossarms are used on steel poles? Is provision made on the poles for additional arms in the future?

Companies using steel arms	28
Companies using wood arms	8
Companies using both steel and wood arms	2
Companies making no provision for additional arms	21
Companies providing for additional arms	14

Cases where provision is made for additional arms are mainly those where tubular steel poles are employed, or where the voltage is below 4400. There are three cases of provision for additional arms at voltages up to 60 kv.

Question: What reasons led to the use of steel poles?

The following reasons for the use of steel poles are given in the order of their importance, as shown by the replies to the question:

1. Appearance
2. Strength
3. Narrow, economical right-of-way
4. Durability
5. Economy
6. City ordinance required them
7. Safety
8. Freedom from fire hazard.

Question: Describe steel poles used.

Four types are reported in use and are listed below, showing the number of cases in which they are used.

Square with four angles latticed together	17
Channels or two angles latticed together	12
Steel tubular	9
Triangular, U-shaped channels latticed together	3

Question: Are self-supporting poles used for angular loads or are corner poles guyed?

Replies indicating corner poles are guyed	25
Replies indicating poles are self-supporting	15

Of the latter group two companies limit self-supporting poles to a 5 or 10-degree angle, although the majority use heavier construction to carry heavy angles, which would ordinarily require guying.

Question: To what extent has it been necessary to guy steel poles to take care of longitudinal stresses?

No longitudinal guys used	20
Guys each mile or for heavy strains or in marshy ground	8
Guys used for deadends or railroad crossings only	2

Question: Are poles designed to carry torsion from broken wires and from deadend conditions?

Designed to carry torsion due to broken conductors and deadends	18
Designed to carry torsion due to broken conductors only	4
Not designed to carry torsion	11

Question: What factor of safety and what unit stresses were used in the design?

Very little data is available on safety factor and unit stresses.

Out of 12 replies 7 use factor of safety of from 1.5 to 2; 4 use factor of safety of from 2 to 3; 1 uses factor of safety of 4.

The unit stresses employed range from 18,000 to 30,000 lb. per sq. in, the most general figure used being between 18,000 and 20,000. The tendency seems to be to use a low factor of safety of approximately 1.5, and to specify the strength of the pole, thus assuring it will not be overloaded.

Question: Are poles set in earth or concrete?

Set in concrete	31
Set in earth	4
Set in either earth or concrete	5

Question: Is any special protection against corrosion used at the ground line?

Companies reporting no protection used	15
Companies reporting concrete footings used as protection	11
Companies reporting protection by paint or galvanizing only	10
Companies reporting protection by steel collars	5
Companies reporting protection by asphalt or pitch	3

Concrete footings extending several inches above the ground line is the practice referred to in the second group of replies. Trolley poles are the only poles protected by steel collars. Asphalt or pitch is used either on top of concrete foundations which extend above ground, or around the steel when concrete footings are below the surface.

Question: Describe the method used in transporting and setting steel poles.

Shipped same as wood	16
Shipped knocked down	12
No data given	12

In general steel poles are shipped the same as wood, especially for the smaller sizes. The larger size poles as well as the galvanized poles are generally shipped knocked down, while painted poles are assembled as much as possible before shipping.

Set with gin pole or piece by piece	16
Set the same as wood poles	9
Set with derrick	7
No data given	8

In some cases poles are assembled on the ground and are set by using the foundations as a hinge and raising the top to a vertical position by means of pikes.

Question: What is practice in stepping poles?

Replies indicating no steps used	28
Replies indicating steps are used	9
Replies indicating no data	3

In general steel poles are not stepped. This is due either to the ease with which some lattice poles may be climbed or to the fact that tubular steel poles are accessible with ladders.

Question: What special construction has been provided to minimize the possibility of climbing by unauthorized persons?

Replies indicating no precautions taken	28
Replies indicating inaccessible steps (i.e., 8 ft. above ground)	7
Replies indicating wire netting or steel plates were used	5

The last group uses netting or plates to cover up accessible lattice work. In several cases the companies depend entirely upon danger signs to give the necessary protection.

Question: Are all poles equipped with danger signs?

Replies indicating no danger signs used	22
Replies indicating danger signs are used	18

Of the first group, sixteen employ steel poles to carry fairly low voltage wires.

Question: Are steel poles occupied jointly with communication companies? What is voltage limit of electric lines in such joint occupancy?

Steel poles are rarely occupied jointly with communication companies. Only four cases were found in all the replies, the voltage limits of the distribution lines in these cases being between 2300 and 7500.

Question: Are larger insulators used on steel poles than for the same lines on wood poles?

Companies using no larger insulators than for wood poles	25
Companies using larger insulators	13
Companies giving no data	2

Practically the only cases where larger insulators are used is in suspension type construction at fairly high voltages, in which cases an extra unit is added.

Question: Are poles protected by painting or galvanizing?

Companies protecting poles with paint......	22
Companies protecting poles with galvanizing..	11
Companies protecting poles by either paint or galvanizing, depending on conditions......	5

The general practice seems to be to protect steel poles by means of paint. Galvanizing is gradually becoming more popular, however, on account of its long life under proper conditions.

The maintenance cost of galvanized structures is considerably less than that of painted structures, which must be repainted every two or three years. Under some atmospheric conditions, however, galvanizing is out of the question; as along the sea coast, in railroad yards and terminals, and in heavy industrial districts where the air is charged with sulphur fumes, as for instance in the Pittsburgh district. Under such conditions, the life of galvanizing is very short and a good paint job will outlast it. A pitch paint on a lead base has been found very satisfactory in such cases.

Question: What has been your experience with regard to deterioration of steel poles? Any data relative to the life of the protective covering on galvanized poles will be of special interest.

Galvanizing has been reported which is 30 years old and is still in good condition. Life of paint is reported to be from two to five years. Some cases of deterioration of tubular poles have been reported. Replies indicate the necessity of a protective covering to prevent deterioration in the vicinity of the ground line.

Question: What is practice for grounding poles?

The following tabulation indicates the practice in grounding poles:

Companies grounding poles with plates or rods buried or driven into the earth...........	14
Companies reporting no grounds are used...	11
Companies reporting poles are self-grounding being set in earth or having the lower ends extending through the concrete footing....	10

Question: Describe any special practices or unusual application of steel poles in connection with transmission or distribution lines.

Very few special uses of steel poles are given. The most common seems to be as substation towers; however, there are only three cases of this sort. One reply indicates that the use of steel poles for 120 kv. construction is unusual, this type of line being usually carried on towers. One reply states that a steel pole was used for transportation of a two-circuit 110-kv. line by using a vertical bus and four deadends.

One company reports the use of 5 in. expanded steel poles on curb line construction, using four such poles to form a platform supporting 3-250 kv-a. transformers.

An unusual combination steel and concrete pole has been developed in Australia. The pole consists of two standard steel channels with flanges facing each other, separated by bolts at intervals, the space between the channels being filled with concrete. The pole is much lighter than a reinforced concrete pole of equivalent strength, and is but slightly heavier than wooden poles which it takes the place of. The pole develops great strength due to the supporting action of the concrete between the channels. The pole has only about 50 per cent of its steel exposed, and therefore requires less painting than an ordinary steel pole. Poles of this type have been made which are 99 ft. in height, for flood lighting service, 50 ft. poles having been made for transmission line service.

Question: What is public's reaction toward steel poles as regards appearance?

Of the replies received on this subject, the public opinion of steel poles seems to be favorable, on account of their good appearance.

Replies indicating no opinion given by public.	20
Replies indicating favorable opinion........	13
Replies indicating no serious objection......	4
Replies indicating public does not like them, claiming they look clumsy...............	2
Replies reporting poles were installed because of city ordinance.......................	1

In concluding the report on steel poles the Committee wishes to acknowledge the valuable assistance of Mr. E. A. Van Deusen of the Central Hudson Gas & Electric Corporation, who contributed the discussion of the general considerations relative to the use of steel poles.

THE MANUFACTURE AND USE OF CONCRETE POLES

The increase in price of wood poles within the last ten years has caused most of the large pole using companies to consider the use of substitutes. Among the most interesting of these is reinforced concrete poles. The electric railway companies of this country have made considerable use of this type of pole, and it is coming into extended use in Europe, where the pressure for a timber substitute is even greater than in this country. There has been comparatively little use of reinforced concrete line poles by power companies in America, but the subject will undoubtedly be a very live one in the near future.

Information concerning the manufacture and use of concrete poles has been collected and summarized in this report with the hope that it may be of value, both to those companies already manufacturing concrete poles, and to those who wish to investigate their possibilities for future construction.

Replies to the questionnaire indicate that concrete poles have not been considered adaptable to general use in a distribution system. Most of the concrete poles now in use were made at the places where they are installed, and because of their great weight could not be moved economically with the equipment available in the past. Answers indicate that past installations have been limited to locations where there was good assurance it would not be necessary to move these poles, and to locations where requirements were for greater strength, improved appearance or longer life. In all cases which have come to the attention of the subcommittee, concrete poles have been used for distribution purposes where one or more of the above considerations were particularly urgent.

It seems probable that there is room for considerable improvement in the methods at present employed in manufacturing concrete poles. The use of waterproofed concrete and of rustproofed reinforcement may prove decidedly beneficial in increasing the life of reinforced concrete poles.

Over 300 questionnaires were sent out. Replies were received from approximately 200 representative public utility companies and the following information was gathered from these replies:

Question: Are concrete poles or standards used for any purpose?

Companies using concrete poles......	33
Companies not using concrete poles.	169
Total replies....................	202

List uses of concrete poles.

Are concrete poles manufactured or purchased?

If purchased give name of manufacturer.

	Mfs.	Purchased	Mfg. or Pur.	Total
Users of line poles..	11	5	..	16
Users of street lighting poles	5	9	5	19

Line poles were used for transmission, distribution, trolley, telegraph and street lighting purposes. All information furnished seemed to indicate a tendency to use concrete poles for fairly low voltage (600 volts).

The tabulation shown above indicates that line poles are being manufactured rather than purchased, probably because of the great weight and difficulty encountered in shipping them.

Question: Describe method of manufacture used, illustrating by photographs, if possible. Specifications and descriptions of procedure are especially important. Describe construction of concrete poles —drawings, dimensions, weights and method of reinforcing are especially important.

Virginia Electric & Power Co., Richmond:

Type of pole—Solid square with beveled corners 30 ft., 35 ft. and 40 ft. long, 8 in. top and taper 1 in. in cross section per 10 ft. of length.

Reinforcement—16 ½-in. square deformed steel bars 1 in. below surface, lengths as follows:

Size of pole........	30 ft.	35 ft.	40 ft.
4 rods	30 ft.	35 ft.	40 ft.
8 rods	25 ft.	30 ft.	35 ft.
4 rods	20 ft.	25 ft.	30 ft.

Forms—Wood, clamped to level concrete foundations, forms oiled with paraffin oil and mica dust.

Mix—1:1½:2 using washed sand and washed ¾ in. gravel, only enough water is used to mix properly.

General Procedure—All work is done outdoors, concrete is placed in 3 layers to allow placing of rods which are not bound together. Two men spade and tamp concrete with wooden paddles, this is *very important.*

Curing of Pole—In hot weather poles are covered. Curing wet for few days gives best results.

Virginia Electric & Power Co., Norfolk:

Type of Pole—Solid square with beveled corners, 30 ft., 35 ft. and 40 ft. long, 6 x 8 in. top, taper 1.5 in. in 10 ft. and 2 in. in 10 ft., giving square base.

Reinforcement 24 ⅝-in. deformed square bars buried 1½ in. below surface and kept 1 in. from end of pole. Lengths are given below:

Size of pole....	30 ft.	35 ft.	40 ft.
4 rods..........	29 ft. 10 in.	34 ft. 10 in.	39 ft. 10 in.
4 rods..........	23 ft.	28 ft.	33 ft.
8 rods..........	18 ft.	23 ft.	28 ft.
4 rods..........	11 ft.	11 ft.	11 ft.
4 rods..........	6 ft.	6 ft.	6 ft.

Mix—1:2:3, using gravel. No other information furnished.

Rochester Gas & Electric Corporation:

Type of Pole—Hollow square with beveled corners 22 ft., 25 ft. and 30 ft. long, 7 in. tops with taper of 1.66 in.-1.8 in. in 10 ft. length.

Reinforcement—8 deformed square steel bars held together by bands at intervals. Rods are buried ¾ in. below surface of pole. Lengths are given below:

Size of pole.......	22 ft.	25 ft.	30 ft.
4 ⅝-in. rods......	22 ft.	24 ft. 6 in.	29 ft. 6 in.
4 ¼-in. rods......	14 ft. 6 in.	12 ft.	18 ft.
Number of bands	9	9	14

Forms—Wood covered with sheet metal, with hollow steel core for the center opening, cores are tapered approximately the same as the pole, leaving from 2½ to 3 in. of concrete between the hollow center portion and the face of the pole. Lengths of cores are given below:

22 ft. pole	14 ft. core
25 ft. pole	17 ft. core
30 ft. pole	23 ft. core

The forms are oiled with a mixture of form oil and lard oil.

Mix—1:2¼:2¼, using bank run sand and washed crushed limestone ⅜ in. size. Enough water is used to give a 7 or 8 in. slump, which gives the concrete a compressive strength of about 2800 lb. per sq. in. in 28 days. The fineness modulus of the mixed aggregate is 4.2.

General Procedure—All work is done indoors in a special plant. The reinforcing cage is held in place by resting on cores for pole stop holes; these holes are later plugged up. Concrete is placed by dumping from a bucket carried by traveling crane.

Curing of Poles—Poles dry for 20 hours inside the plant, after which they are piled outside, where they lie for at least 30 days before being used.

Weight of poles:

22 ft.	1650 lb.
25 ft.	1850 lb.
30 ft.	2400 lb.

Kisse Pole (German Design)

Type of Pole—Shaped like a three-pointed star with hammer-shaped ends on each arm, 20 ft. to 60 ft. or more in length, taper varying for various poles.

Reinforcement—13 round steel rods, four in each arm and one in the center. Rods are of smaller size at top of pole than at bottom, to conform with decreasing bending modulus. Rods are butt welded together and spaced by triangular rings and bound together with spiral windings spaced 2 in. apart. Triangular rings about 3 ft. apart space the three legs of the pole and furnish climbing steps. The rods are spaced 0.59 in. from the surface.

Forms—Horizontal folding forms, with electric hammers arranged to vibrate them while concrete is being placed, giving very dense concrete.

Weights—See Table I.

General: In the mixing of the concrete used for these poles trass is used as an admixture to give increased strength and density as well as improving the weather resisting qualities.

TABLE I

WEIGHT OF KISSE POLES

Length in Feet	Strength of Pole				
	4000 lb.	3000 lb.	2000 lb.	1500 lb.	1000 lb.
20	1700 lb.	1350 lb.	990 lb.	880 lb.	680 lb.
25	2250	1830	1370	1175	900
30	2900	2400	1840	1600	1225
35	3700	3000	2330	2100	1570
40	4500	3700	2900	2600	1950
45	5400	4500	3560	3200	2425

Westinghouse Hollowspun Poles:

Type of Pole—Hollow round from 20 ft. to 45 ft. long, 5 3/5 to 8¼ in. tops, taper 2½ in. per 10 ft. of length.

Reinforcement—A steel cage composed of rods and bands wired together with a spiral wired to the rods, spacing of spiral varies with the strength of pole.

Forms—Cast iron split so that reinforcing can be placed inside, forms are capable of being revolved in horizontal position.

Mix—1:1:2, using sand and gravel by weight. Fineness modulus of aggregate is 4.5, enough water is added to give workable mix, the minimum time of mix being 5 minutes.

General Procedure—The reinforcing cage is placed in the form and supported by concrete buttons which hold rods 1 in. from surface. With the form in a vertical position, a definite amount of concrete is added, the form is rotated in a horizontal position for 10 or 15 minutes, after which the water is allowed to run out of the hollow center position, when it has collected, the resulting concrete is dense and dry, insuring high compressive strength.

Curing of Concrete—Poles are cured 3 hours in a steam pit at 150 to 170 deg. Fahr., then removed from the form and cured wet 14 days. After 28 days the pole is ready for shipment.

Weight—See Table II.

TABLE II

TECHNICAL DATA FOR THE VARIOUS TYPES OF HOLLOWSPUN CONCRETE POLES

Class No.	Length of Pole, Ft.	Diameter of Pole		Weight of Pole, lb.	Recommended Working Load Safety Factor —3.0			Maximum Working Load Safety Factor —1.5			Calculated Elastic Ult.	
		Top, In.	Butt, In.		Load, Lb.	Deflec., In.	Max. Bending Moment, Ft. Lb.	Load, Lb.	Deflec., In.	Max. Bending Moment, Ft. Lb.	Limit, Lb.	Load, Lb.
750	30	5¾	13¼	2,100	750	5.8	16,800	1,500	12.7	33,800	1,875	2,250

*Only one test.
†Poles taken from stock one year old.
Ground line to butt end. 30′0″—5′6″
35′0″—6′0″
45′0″—7′0″

Adirondack Light & Power Co., of Schenectady:

Type of Pole—Solid square, 30 and 35 ft. lengths, taper 1 in. in 10 ft., with a 6 in. top.

Reinforcement—Twisted steel rods 1 in. below surface held by bands.

Size of pole	30 ft.	35 ft.
4 ⅝-in. rods	30 ft.	35 ft.
4 ½-in. rods		25½ ft.

Forms—Wood.
No other information furnished.

Philadelphia Electric Co:

Type—Solid round 40 ft. long, 8 in. top, taper 1¼ in. per 10 ft. of length.
Reinforcing—8 ¾-in. deformed bars.
Weight—3700 lb.

Toronto Hydro Co.:

Type of Pole—Solid square, beveled corners, 24 ft. long, 5 in. top, 8 in. bottom.
Reinforcement—4 ⅜-in. twisted steel rods ¾ in. from surface. Held together by 5 sets of diagonal braces. Held in forms by wire support.
Forms—Wood.
Mix—1:2:4, using sand and crushed stone ¼—¾ in. size.
Weight—1100 lb.

Pennsylvania Railroad:

Type of Pole—Solid square 35—55 ft. long, taper 1 in. for 10 ft. length.
Reinforcement—¾—1⅛ in. rods, depending on size of pole, banded together to form skeleton frame.
Weight—35 ft., 5,300 lb.
55 ft., 17,300 lb.

Question: What provisions are made during manufacture for crossarms, guys and other attachments?

Crossarms are provided for by gains, holes or bronze plates, cast in poles. Extra holes provide for other attachments. Holes are cast by means of cores of steel or paper. When paper tubes are used they are left in place after manufacture.

Question: Is provision made for removing pole steps or are they inserted at the time pole is cast?

Steps are not used in two-thirds of the cases, only one company casts steps in the pole, all others cast holes for removable steps but seldom use them, because the work is usually done from ladders and tower wagons.

The Kisse pole uses the spacer rings for steps. Although these rings are three feet apart, climbing is said to be easily accomplished by using one's knees to climb from one step to the next.

Question: What is the number of concrete poles used each year for each purpose?

Only five users could give data on yearly use of concrete poles. Eleven users have not made or purchased poles for a period of from 3 to 14 years. Yearly production is given below for various companies.

	Per Year
Bureau of Electric Service, Milwaukee	600
Rochester Gas & Electric Corp	1,600
Virginia Electric & Power Co., Richmond	55-310
Virginia Electric & Power Co., Petersburg	50
Virginia Electric & Power Co., Norfolk	35

Question: What has been your experience with regard to deterioration of concrete poles? Describe in detail, giving causes and any remedies adopted.

Twenty users reported on deterioration experience with various kinds of concrete poles. Thirteen users reported poles satisfactory, showing no deterioration in from 5 to 17 years. Two poles are reported in Schenectady which are 30 years old and are in good condition. Seven users reported some deterioration, the causes being as follows:

1. Steel reinforcing too close to the surface, i.e., less than ¾ in.
2. Porous concrete due to the use of too much water at time of mixing.
3. Voids in concrete due to insufficient working or puddling of concrete after placing in forms.
4. Improper curing, i.e., allowing poles to dry instead of keeping them wet for the first ten days after manufacture.
5. Overloading, which is shown up by the appearance of evenly distributed cracks across the pole on the tension side, usually at or slightly above the ground line.

The first 4 items all cause spalling or cracking of concrete away from the reinforcing. When cracking has commenced, frost action causes progressive deterioration.

The remedies for these causes of deterioration appear to be:

1. Steel should be at least ¾ in. below the surface, preferably 1 in.
2. Concrete mixture should be waterproof, this is done by designing the mix for a compressive strength of 3000 lb. per sq. in.
3. Concrete should be worked and puddled after placing in forms, to prevent voids.
4. Poles should be cured damp or wet for at least 10 days after initial set; this alone strengthens the concrete 75 per cent over dry unprotected curing.
5. Poles should not be loaded beyond the strength for which they are designed.

Question: Describe method used in transportation and setting concrete poles. Give depth of setting for various heights.

Concrete poles are generally transported on trailers, similar to wood poles. Long poles may have a stiff, wooden member placed between trailer and truck to prevent excessive deflection. Eight of the users reported poles are set by using a gin pole or derrick. Five of the users reported poles are set by the same method as used for wood poles. Depths used for setting concrete poles vary from 1/5 to 1/7 the pole height, the majority of the users set poles about 1/6 the pole height. One user reported 6 in. greater depth for concrete poles than for wood.

Question: Are any special precautions used by linemen working on concrete poles?

In the majority of cases no special safety precautions are used except that work is generally done from ladders or tower wagons. A man working on a pole is considered to be in contact with a fair ground.

Question: Are wooden arms used?

Seven of fifteen users of concrete poles use wooden arms. The remainder use the following:

5 use no arms,
1 uses 5 ft. channel arm,
1 uses concrete crossarm,
1 uses 10 pin crossarm.

Question: Are larger insulators used on concrete poles than for the same lines on wood poles?

Fifteen of sixteen users do not use larger insulators on concrete poles than on wood poles.

Question: Can you give data on actual strength of concrete poles used based on tests to destruction?

Deflection curves for two types of Westinghouse Hollowspun poles, furnished by the Bureau of Electric Service of Milwaukee, are included in this report. Tests conducted at Milwaukee using Westinghouse Hollowspun are described on pages 165-167 of the July, 1927, issue of "Concrete Highways and Public Improvements." Two sets of curves and one table of test data are included in this report. Curves showing results of tests on 22 ft. and 25 ft. hollow square concrete poles made by the Rochester Gas & Electric Corporation are included in this report. All test data indicate that the strength of the pole is entirely dependent upon the steel reinforcement. As long as the elastic limit is not exceeded, the pole will return from any given deflection without apparent damage to the pole.

An investigation conducted by the Power Distribution Committee of the American Electric Railway Engineering Association brings out the following facts in connection with the strength of concrete poles:

1. Failure of a pole is always due to stretching of the reinforcing rods of the tension side.
2. A failure is always preceded by the appearance of hairline cracks in the concrete on the tension side, at rather frequent intervals from the ground line up.
3. It is advantageous to use a high grade of reinforcing steel to secure the maximum tensile strength.
4. Plain round reinforcing rods are essentially as satisfactory as twisted or other rough rods, because, in general, the rods will elongate before they slip in the concrete.
5. A larger number of small rods is preferable to a small number of large rods, as a better distributed reinforcement may be secured for a given amount of steel, and a better bonding contact surface is presented to the concrete.
6. The reinforcement need not be uniform throughout the length of the pole, but may be stepped off as the top of the pole is approached.
7. A pole with uniform reinforcement will break at the ground line, while one with tapered reinforcement will break at some point above the ground, depending upon the taper of the reinforcement.
8. A concrete pole has an element of safety in it, as a failure of the pole will not, in general, allow it to fall to the ground. It is difficult at times to pull over a pole after failure, even though it is inclined at a large angle from the vertical.

Question: Are concrete poles occupied jointly with any communication companies? What is voltage limit for electric lines in such joint occupancy?

Five of fifteen companies report joint occupation with communication companies, although two of these were fire alarm and police signal systems. The voltage limits for three cases of joint occupancy are 300 volts, secondary, 120-240 volts and 2300 volts.

Question: Has the use of concrete poles enabled you to defer underground construction in cities and villages? Explain how.

Three of fourteen companies report that concrete poles have helped defer underground construction by providing an overhead distribution system of satisfactory appearance. The majority report that concrete poles have not helped to defer underground construction.

Question: What are relative costs on wood and concrete poles?

Concrete poles appear to cost 1½ to 3 times as much as wood poles. One user reports cost as $30 more than wood poles, another reports from 3 to 15 times the cost of wood poles. Westinghouse Hollowspun poles are reported to cost approximately the same as tubular steel poles.

Table III indicates the estimated cost of furnishing Kisse poles, costs are estimated inasmuch as a pole plant has not yet been built in this country.

TABLE III

ESTIMATED COST OF KISSE POLES F.O.B. NEW YORK CITY

Length in Feet	Strength				
	4000 lb.	3000 lb.	2000 lb.	1500 lb.	1000 lb.
20	$28.50	$25.00	$20.50	$17.50	$15.00
25	39.00	34.50	28.00	24.00	22.00
30	51.50	44.00	36.50	30.50	28.00
35	64.50	56.50	46.00	39.00	36.00
40	78.00	69.50	55.50	49.00	43.00
45	97.00	82.50	66.00	60.00	53.00

One eastern company reports the cost of hollow square reinforced concrete poles as follows:

Size	Cost
22 ft.	$16.10
25 ft.	18.40
30 ft.	21.85

Question: Why do you consider concrete poles superior to steel or wood poles?

Reasons for considering concrete poles superior to wood or steel poles are given below:

1. Good appearance.
2. Durability if properly manufactured and loaded.
3. Low maintenance.

One user reports concrete poles are unsuitable for use in city streets because of changing street lines, the poles being unhandy to move. Our reply from Fall River, Mass., reports that concrete poles cannot be used because of a State law which states that any type of pole other than wood which carries wires of over 500 volts must be marked "Dangerous."

In the design and manufacture of concrete poles the following factors should be considered.

1. It is an advantage to use high grade reinforcing steel.
2. Poles should be designed so that the maximum load carried will be below the elastic limit.
3. The concrete used gives the pole its enduring properties, and the design and manufacture of the mixture should be carried out carefully. A mixture designed for 3000 lb. per sq. in. compressive strength will be watertight and will not be affected by the elements. The materials used should be of the best, and placing and curing of the concrete should be done with the greatest care.

In conclusion, it is apparent that concrete poles properly designed and manufactured give a very satisfactory product with an indefinitely long life. To insure successful manufacture of concrete poles it is recommended that "Specifications for the Manufacture of Reinforced Concrete Poles" be consulted. These specifications were the work of the Power Distribution Committee of the American Electric Railway Association in 1925. Also for successful production and manipulation of concrete, it is suggested that "Design and Control of Concrete Mixtures" (Second Edition) be consulted. This practical pamphlet is published by the Portland Cement Association. The principles covering the design of concrete poles have been collected and published by the American Electric Railway Engineers Association.

RECOMMENDED PRACTICES FOR DESIGN AND CONSTRUCTION OF RURAL LINES

Scope of Work

A. These recommendations, while not complete, are intended to embody the general features of rural lines and to point out where the construction may differ from that of the generally accepted short span construction used in lines constructed in urban territories. The present practice of various operating companies now serving rural territories has been used as the basis for these recommendations, together with the requirements of Handbook No. 3 of the Bureau of Standards. (Fourth Edition of the National Electrical Safety Code). The recommendations in the main are general only, though they have been made somewhat more detailed where it seemed desirable. Such details of construction as tend to decrease the cost of the line without unduly sacrificing strength or tending to increase maintenance costs have been emphasized.

B. This report is not intended to set up standards of construction, but to serve purely as a guide for rural line construction.

Definitions

A. The definitions as given in Handbook No. 3 of the Bureau of Standards (Fourth Edition of the National Electrical Safety Code) apply to the terms used in these recommendations. In addition, the following definitions are given for terms not included in the Code List.

B. For the purpose of this report, a *rural line* is a line of low or medium voltage traversing rural territory and supplying electric service to farms, individual customers, small groups of customers, villages or other scattered enterprises located in rural territory. Such lines may be constructed within the corporate limits of cities when the character of the load so warrants, and the construction of the generally accepted short span line used for urban distribution is not economically justified; and, conversely, all lines in rural territory are not necessarily rural lines. Rural lines in general will be of such voltage that one transformation can be made direct from the primary voltage to a voltage suitable for the customer's use. Rural lines may be extensions of existing urban or suburban distribution systems, or may be independent circuits from stations or substations.

General Considerations

A. In general, all construction work should be of a permanent character and of good workmanship. Any skimping of guying, digging pole holes to insufficient depth, making poor joints and other temporary make-shifts to hasten the work should be avoided, as should laxity in securing privileges for pole and anchor locations and tree trimming rights, which cost more for repairs and rebuilding and cause more annoyance than permanently built lines for which rights are secured in a binding and workmanlike manner.

B. In making a decision as to the character of construction justified, it should be borne in mind that the use of the higher grade material results in longer life in general, while the use of the cheaper grade of material means shorter life and higher maintenance costs. The various factors should be evaluated and an economic balance reached in determining the grade of construction for rural lines in any particular instance.

C. New work should be laid out, as far as economically practicable, to take into account the reasonable growth which may occur, instead of limiting its capacity to immediate needs.

Specific Considerations

Lines, General

A. The construction features of the line should conform with the rules of regulatory bodies having jurisdiction; and where no such rules exist the provisions of Part 2 of the National Electrical Safety Code for the appropriate grade of construction may be used as a guide.

B. Lines should consist of straight sections with as few angles as possible, and these angles, where they are necessary, should be turned on the minimum number of poles. Long curves should be avoided, where practicable, because of the greater cost of construction due to the increased number of guys, double arms and dead ends.

C. These recommendations in general apply to rural lines when alone. When such lines are concerned with crossings, conflicts or joint use with communication lines, or with crossings over railroad tracks, such additional requirements as may be necessary should be complied with.

Location of Lines

A. Where at all practicable rural lines should be built along highways so that the greatest number of customers may be reached, and so that highway lighting may be supplied as required later. If, in some cases, it is deemed advisable to build over private right-of-way, it is recommended that all private right-of-way be fully protected by easements or approved agreement, the clauses of which should in no way be detrimental to the operation or construction of the line.

B. Lines should be located on one side of the highway, where practicable, thereby avoiding crossing from one side of the road to the other. Where communication and supply line circuits on the same highway are not to occupy joint poles, or where the supply line is alone on a highway, the supply line should be placed on one side of the highway throughout as far as practicable, so that one side

---

Publication No. 289-16, Serial Report, Overhead Systems Committee.

of any section of a highway will be available as the communication side and one side as the supply side.

C. Where it is necessary for supply and communication lines to occupy the same side of a highway, joint use is generally preferable to over-building, where such joint use is justified by considerations of safety, economy and convenience, and the condition and character of the circuits permit, and where satisfactory agreement between the parties concerned as to terms and conditions can be reached.

D. In making a decision as to the location of a rural line on a highway, or as to the allocation of costs when the construction of both communication and supply lines along the highway make necessary changes in existing lines, general principles should be followed as outlined in the reports of the Joint General Committee of the National Electric Light Association and the Bell Telephone System on the "Physical Relations Between Electrical Supply and Communication Systems."

E. If it becomes necessary to locate more than one line of poles on the same side of a highway, the pole locations should be such that no conductors of any line will come within 3 ft. of the pole of another line, nor within 4 ft. of a conductor of another line, at 60 deg. fahr. and no wind. These clearances do not apply when the conductors of both lines are attached to the same poles; under such conditions the clearances for jointly used lines apply.

For some conditions of span length or conductor sags it may be necessary to increase the above clearances. Under any condition the clearance requirements of Rule 234 of the National Electrical Safety Code, Fourth Edition, which also provides for minimum safe clearances from line conductors to buildings and bridges, should be complied with.

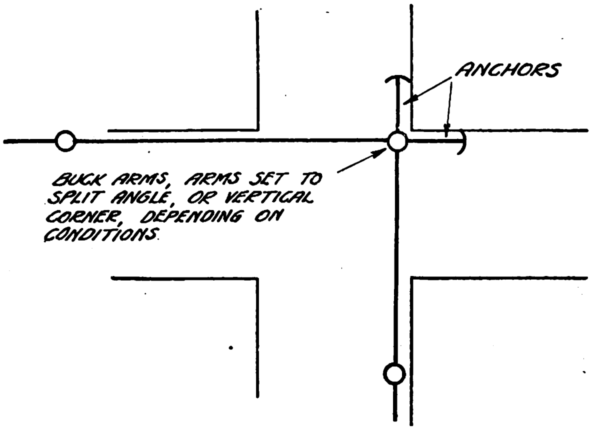
Location of Poles

A. Poles located on public highways should be set as near as practicable to the edge of the right-of-way or property line, in order to allow for future widening of the highway. Poles should always be located so as not to obstruct the flow in drainage ditches, and preferably should be set between the ditch and the property line. Where the ditch consists of a wide borrow-pit from which material was taken to grade the roadway, it may be necessary for the poles to stand in the back edge of the ditch, or close to the foot of the back slope, adjacent to the property line. Whenever local statutes or ordinances govern the location of pole lines on public highways, the necessary advance authority or approval should be obtained from the proper State, county, town or municipal officials.

B. In order to obtain the maximum clearance of line and service wires from trees and above ground, especially in long span lines, poles should be located on the top or shoulder of a rise of ground rather than in a hollow; as near as practicable to any tree in the line, unavoidably passed through or over; and at such points as to make service drops as short as possible.

C. Poles at crossings, angles and other points where guys will be necessary should be located so that there will be no obstruction to guying, and where the guy anchor may be placed well away from the pole. Where possible, guy anchors should be placed at a distance from the pole equal to or greater than the height from the ground to the point of attachment of the guy on the pole.

D. In general, corners should be turned on a minimum number of poles, in accordance with the following sketches. Poles for corners or angles should be located so as to obtain good guying facilities; guys should be attached to anchors in preference to guying to a stub or to the adjacent pole, except where proper clearances cannot be obtained otherwise.



ANCHORS
BUCK ARMS, ARMS SET TO SPLIT ANGLE, OR VERTICAL CORNER, DEPENDING ON CONDITIONS

FIG. 1.

For more detailed information on corner construction and guying, see Section 11, Overhead Systems Reference Book, as issued by the Overhead Systems Committee, Engineering National Section, National Electric Light Association.

The one pole corner construction, as shown in Fig. 1, is used in general where the length of the curve of the line is short, and where the angle turned is such that the complete turn can be made on one pole. The mechanical loads imposed and the clearance necessary between phases of the circuit will determine whether buck arm construction, a single or double arm set to split the line angle, or vertical construction at the corner will be necessary.

In the construction shown in Fig. 2, two main corner poles are located at an equal distance from the center of the curve, and the adjacent poles spaced as nearly equal as practicable. This construction is

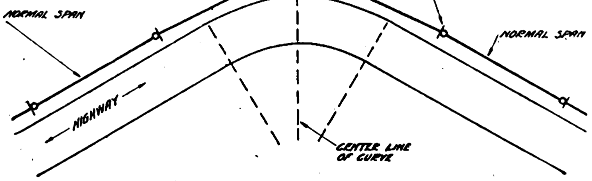


FIG. 2.

used where the length of the curve of the line is great enough so that the corner cannot be turned on one pole. It may also be necessary where short spans are required at a corner to prevent overhanging of private property and other cases of this nature. The type of construction required is determined as in Fig. 1.

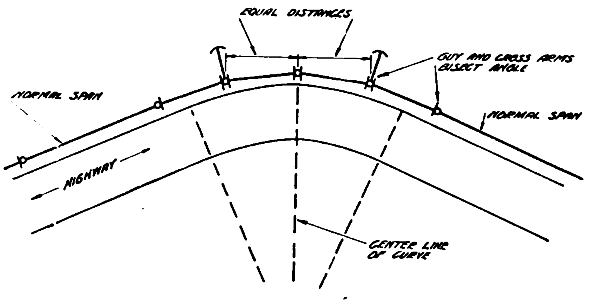

FIG. 3.

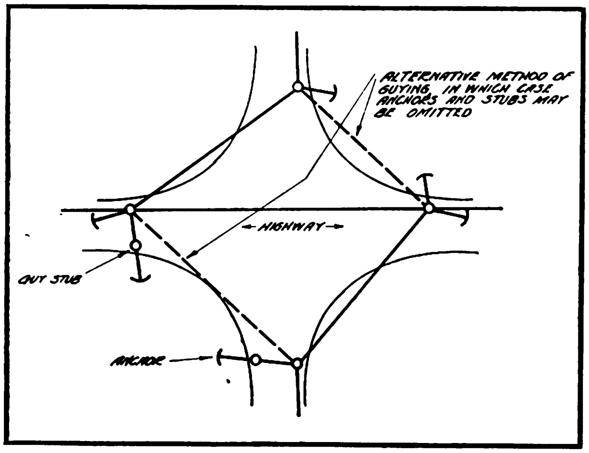
In the construction shown in Fig. 3, the main corner pole is located at the center of the curve, and adjacent poles are spaced as nearly equal from the main corner pole as practicable. This is a variation of the construction shown in Fig. 2.



ALTERNATIVE METHOD OF GUYING, IN WHICH CASE ANCHORS AND STUBS MAY BE OMITTED
HIGHWAY
GUY STUB
ANCHOR

FIG. 4.

The type of construction shown in Fig. 4 is used at long radius road intersections.

The type of construction shown in Fig. 5 is used where it is necessary to cross from one side of the highway to the other.

For further detail as to construction and guying, refer to Section 11, Overhead Systems Reference Book.

Voltage

A. In general, it is impossible to establish a uniform voltage for rural lines, as the selection of voltage to be used will often be governed by the local line voltages available in that vicinity. Rural lines built as extensions of existing feeders should usually operate at the voltage of the feeder, provided such voltage is adequate to handle the load.

B. It is recommended that, with all rural lines of any considerable extent, or possible of extension to such, consideration be given to building for ultimate operation at one of the higher voltages, 6900 or above, according to the future load possibilities and standards of the company concerned.

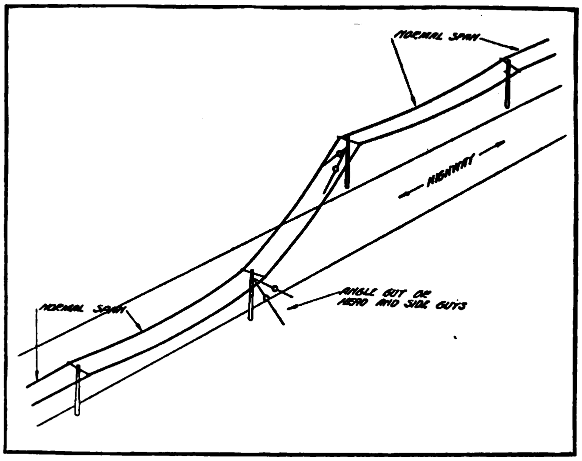


FIG. 5.

C. It is also recommended that each company operating rural lines give consideration to establishing a standard voltage not lower than 6900 as a basis for the ultimate operation of lower voltage rural lines, and as the operating voltage of rural lines built as new projects whose voltage is not governed by that of an existing system.

D. The voltages given in Table I may be considered as available for rural circuits. The voltages are based upon 115/230 volts being available for the customer, and transformer ratios of 10 to 1, or multiples thereof. These voltages correspond to the ratings of transformers usually supplied by the manufacturers for customers' service.

TABLE I

Single Phase or Three Phase Delta	Three Phase Star
2,300	4,000
4,600	8,000
6,900	11,950
11,500	.....
13,800	.....

E. Table II, showing loads and distances for various sizes of conductors and voltages is given as a guide to the selection of voltage and size of conductor for any particular situation to be considered. This table shows the limitations of the lower voltages in amount of load which can be handled at the usual rural distances, and also shows the great advantage of selecting the higher voltages especially for the ultimate loads which will develop in rural territory.

Span Lengths

A. In general, within certain limits, any increase in span length of a line will decrease the first cost of construction because of the smaller amount of

TABLE II

TABLE OF LOADS AND DISTANCES SHOWING KILOWATT-MILES FOR VARIOUS CONDUCTOR SIZES AND VOLTAGES

Voltages		Product of Kilowatts and Miles for Different Conductor Sizes

2,300	......	48	69	96	128
	2,300	96	137	189	251
4,600	......	193	277	384	511
	4,000	290	415	572	760
	4,600	384	548	756	1,004
6,900	......	434	625	864	1,150
	6,900	864	1,235	1,702	2,260
	8,000	1,160	1,656	2,285	3,060
11,500	......	1,207	1,735	2,400	3,200
	11,500	2,400	3,430	4,730	6,280
	11,950	2,590	3,700	5,110	6,780
13,800	......	1,737	2,500	3,456	4,600
	13,800	3,460	4,940	6,820	9,040

NOTE: The above table is based upon 5% line drop and 80% power factor with load concentrated at the end of the line. Conductor separations of 30" single phase and 29½" three phase have been used, as illustrated in Fig. 6.

To obtain the concentrated load which can be carried with a given conductor at any distance, divide the corresponding value from the table above by the distance in miles, which will give the desired result in kilowatts.

For uniformly distributed total loads use twice the values shown in the above table for concentrated loads.

material and labor required for supporting structures. There are certain factors which affect the situation, however, and certain limits beyond which it is inadvisable to go. For instance, longer spans require greater conductor sags to keep the conductor stresses within allowable limits; greater sags in turn may require greater separation of the conductors on the crossarm and hence larger and more costly crossarms; or the sags may be great enough to require longer poles to maintain the necessary clearance above ground, thus resulting in higher costs. Sags in long span lines may be reduced somewhat by the use of conductors having higher tensile strength than hard-drawn copper. However, the difference in conductivity of conductors of different tensile strengths must be considered in order that the allowable voltage drop will not be exceeded. All of these factors must be taken into consideration in deciding on span lengths.

B. Lines having normal span lengths of 250 and 300 ft. have been, and are now being, successfully operated by companies in various parts of the country; under some conditions even greater span lengths are feasible. These span lengths sometimes must be decreased in certain parts of the line, such as crossings, angles in the line, at points where there is excessive tree interference, and other similar cases.

C. Lines may be originally built having spans on the order of 250 and 300 ft. in length, and later, when additional conductors must be added, additional poles may be set at the mid-span points, thus cutting span lengths to about the average used for urban distribution.

D. For lines built for joint use with communication companies, the span lengths must be such as to satisfy the requirements of both types of line.

E. Table III gives the minimum gage sizes for supply line conductors, in accordance with the requirements of Handbook No. 3 of the Bureau of Standards (Fourth Edition of the National Electrical Safety Code) for rural lines.

TABLE III

MINIMUM GAGE SIZES FOR SUPPLY LINE CONDUCTORS

Material	Urban	Rural
Soft copper....................	6	8
Medium or hard drawn copper..	8	8
Steel..........................	9	9
	Urban and Rural	
	Spans 150 Feet or Less	Spans Exceeding 150 Feet
Stranded Aluminum:		
Not reinforced..............	1	0
Steel reinforced..............	6	4

The Handbook recommends that, except as modified in Table 23, Rule 261F2 of the Handbook, these minimum sizes of copper and steel be not used in spans longer than 150 ft. for heavy-loading districts, and 175 ft. for medium and light-loading districts.

Poles, Type and Size

FIG. 10.

lines. The type of pole best suited for use by one operating company is not necessarily the best for another operating company in a different geographic location, because of the varying climatic conditions and the availability of material.

B. Poles of such length should be selected so as to provide the clearances from ground or track rails, and from poles and conductors of another line, as illustrated in the following drawings (Fig. 7-10, inclusive). In building lines along roads having a large amount of tree interference, it should be borne in mind that short poles under the trees or the use of side arm construction, or both, will often be satisfactory and will save the extra expense of poles long enough to carry the conductors above the trees.

C. In choosing poles, both strength requirements and expected life of the pole should be considered. The use of the better grades of poles is advisable in general where probable future growth will require more circuits or circuits of larger conductors to be installed on the poles within a reasonable time. Treatment of poles with a preservative against decay is of advantage in prolonging their life, and consideration should be given to the use of treated poles.

D. Poles should be selected which give adequate strength to meet local conditions. Several States have rules governing the strength of supporting structures, and where such rules exist their requirements should be complied with. In localities where there are no rules establishing pole strengths for lines used in providing rural electric service, the following may be used as a basis for determining the strength of poles to be used:

1. Ultimate fiber stresses of wood poles—

	Lb. per sq. in.
a. Southern yellow pine............	6,800
b. Western red cedar................	5,600
c. Northern white cedar............	3,600
d. Chestnut	6,000

2. When crossings, conflicts or joint use of poles are involved, pole strengths should be greater than the minimum required when lines are alone. The proper percentage of ultimate strengths for crossings, conflicts or joint use will depend on the character of the line concerned.

Table IV gives resisting moments in pound-feet for different ground line circumferences of poles usually used for rural lines, based upon the above values of fiber stress and using 100 per cent of the ultimate strength.

The resisting moment for other values of fiber stress may be determined by multiplying the resisting moment as shown in the table above by the ratio of the allowable fiber stress to the fiber stress used in the table. Values for other pole circumferences and for other fiber stresses may be found in Handbook No. 3 of the Bureau of Standards (Fourth Edition of the National Electrical Safety Code).

TABLE IV

RESISTING MOMENTS FOR WOOD POLES

Circumference at Ground Line in Inches	Resisting Moment for Fiber Stress of (lb. per sq. in.)			
	3600	5600	6000	6800
	lb. ft.	lb. ft.	lb. ft.	lb. ft.
22	10,100	15,750	16,850	19,100
23	11,550	18,000	19,250	21,850
24	13,150	20,400	21,900	24,800
25	14,850	23,100	24,750	28,000
26	16,700	25,950	27,800	31,550
27	18,700	29,100	31,150	35,300
28	20,850	32,450	34,750	39,400
29	23,150	36,050	38,600	43,750
30	25,650	39,900	42,750	48,450
31	28,300	44,000	47,150	53,450
32	31,100	48,400	51,850	58,800
33	34,150	53,100	56,900	64,450
34	37,350	58,050	62,200	70,500
35	40,700	63,350	67,850	76,900
36	44,300	68,900	73,850	83,700

The moment in foot-pounds of the forces acting on a pole should not be greater than the value of the resisting moment of the pole in pound-feet, as determined in accordance with the previous paragraph. To determine the moment in foot-pounds of the forces acting on the pole, multiply together for each conductor the wind pressure in pounds per linear foot of conductor, the span length in feet, and the height in feet above ground of the point of attachment of the conductor to the pole or crossarm. The sum of these values for all conductors will be the transverse bending moment on the pole due to the wind pressure on the conductors. To this value must be added the bending moment due to wind pressure on the pole itself, in order to get the total bending moment which the pole must withstand. To determine the moment in foot-pounds due to the wind pressure on the pole itself, multiply together one-half the height of the pole above ground in feet, the average diameter of the pole in feet, the height of the pole above ground in feet, and the wind pressure in pounds per square foot.

The values of horizontal wind pressure used in the above calculations will depend upon the loading conditions encountered in the locality under consideration. In southern territory where glaze (ice formation on wires) storms do not occur, the loading should be based on the maximum horizontal wind pressure acting upon the actual projected area of the wire. In territory subject to glaze formation the loading should be based upon the maximum horizontal wind pressure acting upon the projected area of the wires when covered with ice.

Tables of loading on wires of various sizes and kinds for different values of wind pressure, with and without ice loading, may be found in Handbook No. 3 of the Bureau of Standards and in other published form. The values given in these tables may be proportionately modified to correspond to the values which it is desired to apply to any particular situation. For example, it has been found in certain localities in the territory classed as the "heavy loading" district that a wind pressure of 4 lb. per sq. ft. of projected area, acting against a conductor covered with ½ in. radial thickness of ice, represents the maximum condition which is likely to occur.

Grading of Line

A. The length of poles in the line should be so chosen that no change of grade will occur in the line which will result in an up-pull of the line wires on the insulators, as shown in Fig. 11, unless the line wires are dead ended.

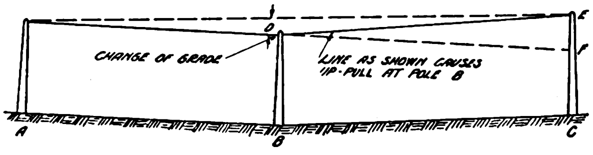

FIG. 11.

B. On level ground and in only slightly hilly country, no abrupt change in line level of more than 5 ft. for 125 ft. spans or 10 ft. for 250 ft. spans should normally be made; in other words, in grading from 35 ft. poles to 50 ft. poles in 125 ft. spans, the order should normally be 35 ft., 40 ft., 45 ft., 50 ft. on level ground. In slightly hilly country or uneven ground, poles of such lengths as to give the same grade should be chosen. This recommendation cannot always be adhered to in very hilly or mountainous country; where such conditions exist, the line grade should follow the general conformation of the ground and should comply as nearly as practicable with Paragraph A above. Unnecessary grading is a waste of money and should be avoided.

C. The change of grade is measured as shown at D, Fig. 11, which, as shown on pole B, is approximately equal to one-half the distance E-F on pole C. The point F may be located by sighting between corresponding marks on sighting rods, which are painted with 1 ft. stripes, and noting the difference on the center sighting rod as shown in Fig. 12 below.

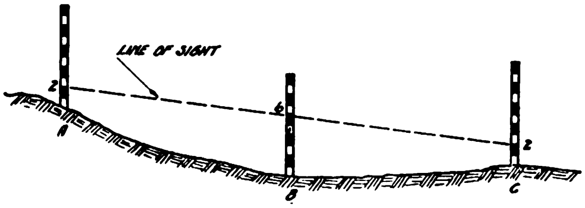

FIG. 12.

Place sighting rods at the pole locations. Sight between corresponding marks on rods A and C, so that the line of sight will cut rod B. In the illustration the 2 ft. mark is selected as a convenient point for sighting on rods A and C, and the line of sight cuts rod B at the 6 ft. mark. This indicates that there is a change of grade of 4 ft. (6 ft. less 2 ft.) at pole B. Variations of the method described may be used to determine the pole heights necessary to eliminate up-pull, to give necessary clearance above high points in the ground between poles, and other cases of this nature.

Pole Framing

A. Poles should have the loose bark removed and all projecting knots trimmed, but they should not ordinarily be shaved. Butts should be sawed off square.

B. All poles should be roofed at angle of 45 deg., where climatic conditions warrant, to guard against the accumulation of water, which is one of the elements necessary to decay.

C. In general only a very shallow gain should be cut. Deep gains should be avoided, as on the small top poles a deep gain materially affects the strength of the pole. It is advisable to cut additional gains or bolt holes on poles treated throughout their entire length, before the poles have received treatment.

D. Before setting, all single pole construction should be completely framed and fitted with crossarms, braces, pins, racks and other fittings wherever practicable. This is usually feasible on rural lines and saves considerable construction expense, as all work on the pole is then done on the ground.

Excavation for Poles

A. Holes for straight line poles should be dug, and the poles set to the minimum depths as shown in Table V.

TABLE V

Length of Pole, Feet	Depth of Pole Setting	
	Setting in Soil, Feet	Setting in Rock, Feet
25	5.0	3.5
30	5.5	3.5
35	6.0	4.0
40	6.0	4.0
45	6.5	4.5
50	7.0	4.5
55	7.0	5.0
60	7.5	5.0
65	8.0	6.0

B. Poles subject to excessive strain, such as stubs, poles at curves and corners and poles set at points where additional strength is required, shall be set 6 in. deeper than specified in the table above for poles 60 ft. and less, and 12 in. deeper for poles over 60 ft. in length.

C. The depth shown in the table should be increased for poles having small ground line circumferences, and poles set on the slope of banks, in marshy ground, in quicksand or in soil having poor bearing qualities. The depths of holes on steep banks should be measured from the low or downhill side of the hole.

D. Where there is any probability of the ground level at the pole location being lowered within a short time, set the poles so that they will be in the ground not less than the specified depths after the new grade is established.

Back Filling and Tamping

A. Care should be taken in back filling to insure a thorough tamping of the fill. Back filling should be carefully supervised as the strength of the line and its appearance after the first few rains depend upon uniform back filling and firm tamping. Only one shoveler should be used, while *two or more* tampers continuously tamp down the filling. When available or where the soil is soft or unstable, small sized rock, coarse earth or gravel should be used for filling, care being taken to fill all the crevices with earth. After the hole is completely filled, soil should be banked firmly around the pole to provide for settling. If it is necessary at the time of the original back filling to fill the hole with frozen earth, the hole should later be refilled and retamped.

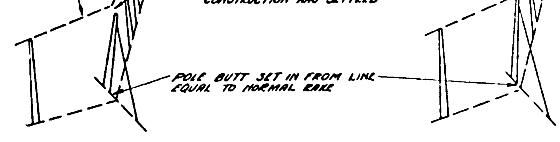
B. Where the depth of the hole has been reduced in accordance with the table for "Setting in Rock" the back fill should be made by wedging in with the digging bar a layer of the larger rock placed edgeways between the pole and the side of the hole, and then firmly tamping smaller rock and gravel or coarse earth into the crevices between the larger rock until all the voids have been filled to near the top of the layer. Continue filling the hole by layers, wedging in as many of the larger rock as possible, until the back fill is completed. Loose earth should be piled around the base of the pole to provide for settling caused by the rain washing the dirt into unfilled crevices in the rock. Where rock is available, this method should be used for settings in soft or unstable earth.

C. In addition to the extra depth of setting in marshy soil or quicksand, it will sometimes be necessary to use various methods to provide sufficient stability where good firm foundation cannot be obtained. These methods may be guying, the use of rock, or of bog shoes. If the soil is quicksand, it is often necessary to use a sand barrel in sinking the holes, the barrel being used to prevent cave-ins.

D. All pole holes should be dug as small in diameter as practicable, and in general shall be only large enough to receive the butt of the pole without forcing and to allow the use of a tamping bar around the pole for the full depth of the hole after the pole is set in place. The holes should be of the same diameter throughout their entire depth. The disturbance of too great an area of earth in digging the pole holes will result in the failure of poles to remain lined up.

Pole Setting and Erecting

A. Poles should be set to stand perpendicularly except at corners, curves and other points of exceptional strain, where they may be given a slight rake against the strain. Where practicable, angle and dead end poles should be raked by setting the butts in toward the strain. When placing guys, pull the tops of the poles a little out of line so that when the load is put on and the guys have settled, the pole tops will come back into line, as shown in Fig. 13.



PULL TOP OF POLE OUT OF LINE WHEN PLACING GUYS
LINE OF LEAD
POLE TOP SHALL BE IN LINE AFTER CONSTRUCTION HAS SETTLED
POLE BUTT SET IN FROM LINE EQUAL TO NORMAL RAKE

FIG. 13.

Crossarms

A. Crossarms used should conform in dimension and material with those illustrated in the Overhead Systems Reference Book and subsequent reports prepared by the Overhead Systems Committee of the N. E. L. A., and they should be securely supported so as to withstand safely a vertical load of 225 lb. at either extremity in addition to the weight of the conductors.

B. For single phase construction it is recommended that two-pin crossarms be used, except where it is planned to add additional conductors later or where additional horizontal clearance between conductors is necessary, in which case either a pole top pin should be provided for or a longer crossarm used.

C. For three-phase, three- or four-wire circuits of flat construction, it is recommended that four-pin crossarms be used, except where sags are such that greater separation at the supports is required. In such cases a six-pin crossarm may sometimes be used. For three-phase, three-wire triangular construction in lines of these voltages, arrangement of the wires in a triangle with equal spacing between conductors is not necessary, and somewhat flat triangular construction, using a pole top pin and either a two- or four-pin crossarm, as shown in the accompanying drawings, may be used. This construction gives greater clearance above ground for a given height of pole than the equilateral type of triangular construction.

D. Double crossarms are recommended at dead ends, corners and other places where extra strength is required.

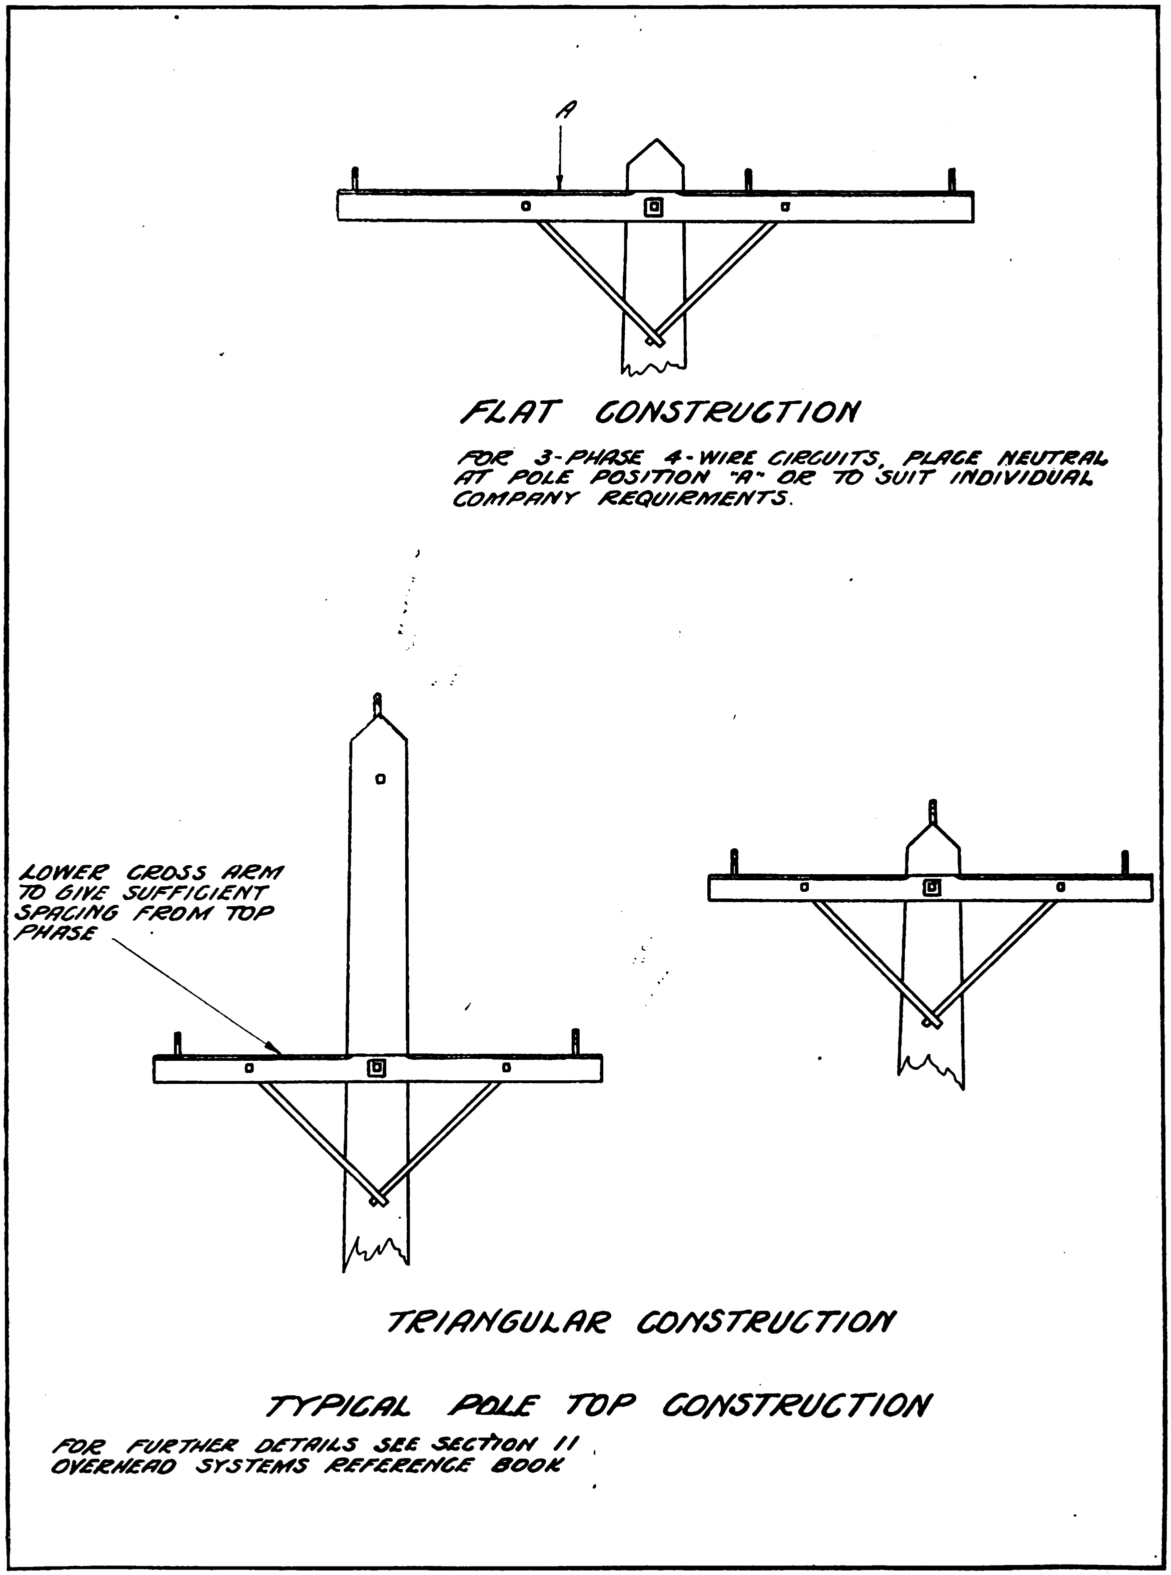
Pins

A. Either wood or metal pins may be used and should comply with the requirements as shown in Section 11 of the Overhead Systems Reference Book and subsequent reports of the Overhead Systems Committee of the N. E. L. A.

Insulators

A. Insulators, if of porcelain, should be made by the wet process. Glass or other material, which will give satisfactory results in respect to mechanical and electrical performance and durability, may be used. All line insulators should conform to the specifications of the American Institute of Electrical Engineers. Experience indicates that it is advisable to use top groove insulators for long span lines.

B. Guy insulators should have a dry flashover voltage at least double the normal line voltage, and a wet flashover at least as high as the normal line voltage between conductors. They should have a mechanical strength at least equal to that required of the guys in which they are installed.



FLAT CONSTRUCTION

FOR 3-PHASE 4-WIRE CIRCUITS, PLACE NEUTRAL AT POLE POSITION "A" OR TO SUIT INDIVIDUAL COMPANY REQUIRMENTS.

LOWER CROSS ARM TO GIVE SUFFICIENT SPACING FROM TOP PHASE

TRIANGULAR CONSTRUCTION

TYPICAL POLE TOP CONSTRUCTION

FOR FURTHER DETAILS SEE SECTION 11 OVERHEAD SYSTEMS REFERENCE BOOK

FIG. 14.

C. An insulator should be located in each guy, which is attached to a pole or structure carrying any supply conductors of more than 300 volts to ground and not more than 15,000 volts between conductors, or in any guy which is exposed to such voltages. This guy insulator should be located from 8 to 10 ft. above the ground.

D. Where a guy attached to a pole is carried over or under overhead supply conductors of more than 300 volts to ground, and where hazard would otherwise exist, two or more guy insulators should be placed so as to include the exposed section of the guy between them as far as practicable. Neither insulator should be within 8 ft. of the ground.

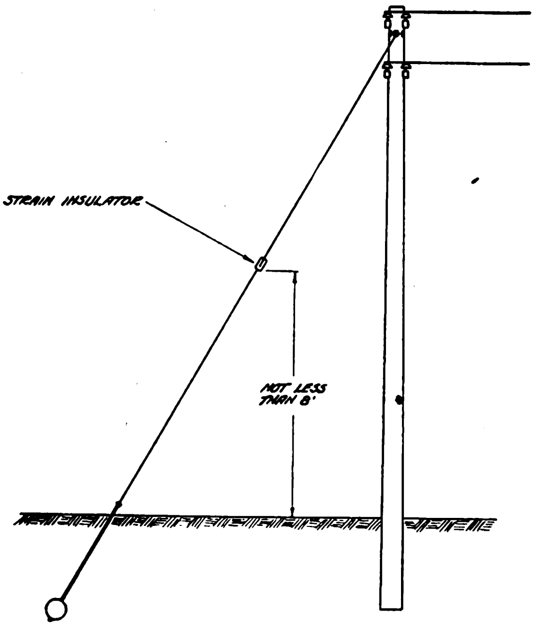
Guys

A. Guys should be installed when the loads imposed are greater than can be safely carried by the poles, and guys will furnish the necessary additional strength, and wherever necessary to counteract any unusual strain which tends to pull the pole or crossarm out of place, as at dead ends, corners, angles in the line and other similar cases.

B. Guys should be used in preference to push braces wherever practicable.

C. In view of the fact that many rural lines must be constructed economically, storm guys may be omitted except where the line traverses a territory for many miles in a straight line; guys at curves and corners often render storm guying unnecessary. When storm guys are attached, dead ends are unnecessary.

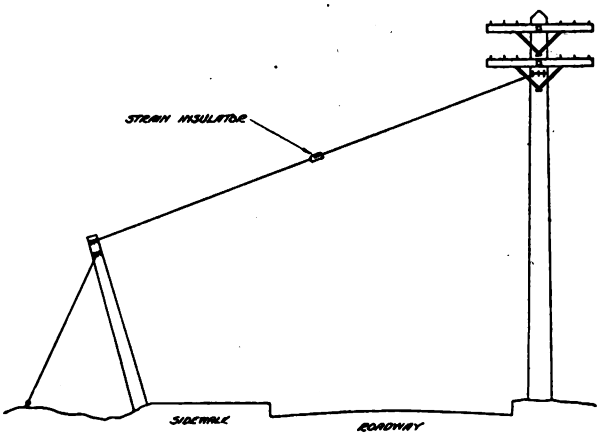
D. The ground end of all guys attached to ground anchors should be provided with a substantial and conspicuous wood or metal guard not less than 8 ft. long where traffic or other conditions warrant.



WHEN INSTALLING TWO STRAIN INSULATORS IN A GUY, ALWAYS MAKE CERTAIN THAT IF A GUY BREAKS AND SWINGS IN TO THE POLE THERE WILL BE AT LEAST ONE INSULATOR BETWEEN ALL LIVE WIRES AND A POINT 8' ABOVE THE GROUND

ANCHOR GUY INSTALLATION

FIG. 15.



WHEN INSTALLING TWO STRAIN INSULATORS IN A GUY, ALWAYS MAKE CERTAIN THAT IF A GUY BREAKS AND SWINGS IN TO THE POLE THERE WILL BE AT LEAST ONE INSULATOR BETWEEN ALL LIVE WIRES AND A POINT 8' ABOVE THE GROUND.

STUB GUY INSTALLATION

FIG. 16.

Anchors

A. Anchors should be set at a distance from the pole at least equal to the height of attachment of the guy above ground, if practicable, and should never be set so that the slope (ratio of lead to the height) is less than 0.33. The nearer the anchor is set to the pole, the less strain it will hold.

B. In locating anchors, good judgment should be exercised. Guys located at property lines, fence corners or other convenient points will be more acceptable to the owners of adjacent property. Anchor locations should be such as to avoid interference with traffic.

C. Either patent anchors or log anchors may be used. The log anchor should be at least 8 in. in diameter and 4 ft. long, and of good sound timber.

Conductors

A. Conductors should be of copper, aluminum cable steel reinforced (A. C. S. R.), copper covered steel, or other material which will not corrode excessively under the prevailing conditions.

B. The use of bare wire is recommended for rural lines. The use of aluminum cable steel reinforced, copper covered steel or other high strength material should be given consideration for long span lines. Conductivity should be taken into account in the selection of conductors.

C. If A. C. S. R. is used, all connections between aluminum conductors and copper conductors should be made with suitable clamps designed for the purpose. At all points where clamps of any type must be used with A. C. S. R., only clamps designed for the purpose should be used.

D. Bare wire may be used for secondaries when on crossarms or when on vertical racks, if the proper spacings are used. In general, where shorter spans are necessary covered wire on vertical rack may be used.

E. Secondary circuits should be of not less carrying capacity than No. 6 A. W. G. copper or No. 4 A. W. G. aluminum cable steel reinforced.

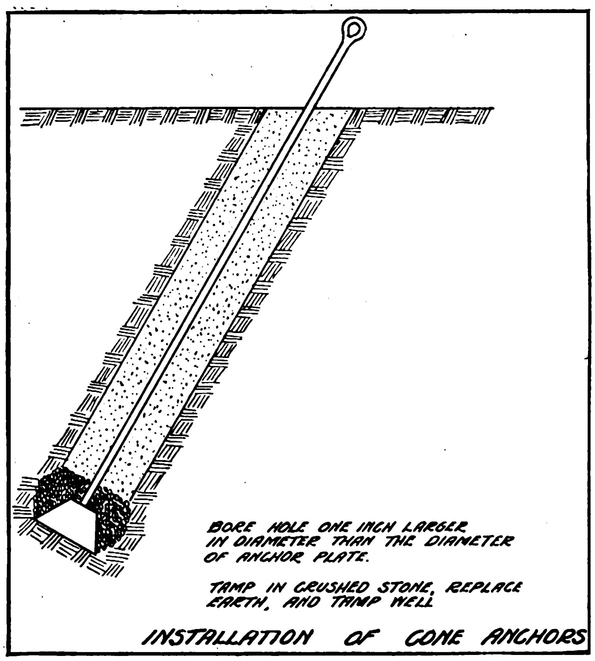
F. Service drops should be not less than No. 8 A. W. G. copper or its equivalent.

Position of Circuits

A. It is preferable that secondary conductors be not placed on the same crossarm with primary conductors.

Sagging of Conductors

A. Table VI gives sags for those sizes of medium and hard drawn bare copper conductors that are likely to be used in the construction of supply lines suitable for rural distribution. These sags are taken from Bureau of Standards Handbook No. 3, Fourth Edition of National Electrical Safety Code.



BORE HOLE ONE INCH LARGER IN DIAMETER THAN THE DIAMETER OF ANCHOR PLATE.
TAMP IN CRUSHED STONE, REPLACE EARTH, AND TAMP WELL
INSTALLATION OF CONE ANCHORS

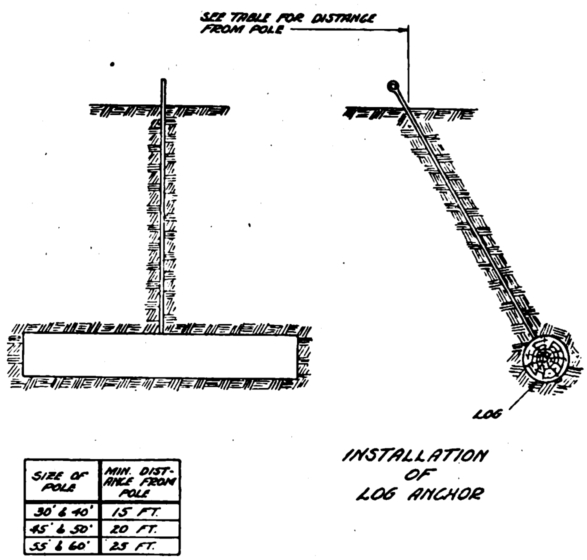
FIG. 17.

B. The sags given herewith are such that under the weather loading conditions specified in the National Electrical Safety Code, the conductor tension will not exceed 60 per cent of its ultimate strength. When lines are involved in crossings with communication lines or railroad tracks, or where they conflict with or are on the same poles with communication lines, sags in accordance with the requirements specified for those cases should be used.

C. Table VII gives the sags for A. C. S. R. (aluminum cable steel reinforced) recommended by the manufacturer for rural line construction.

Ties

A. Conductors should be properly tied to the insulators. Tie wires must have a surface of the same material as the line conductor in order to prevent electrolytic action; should have no sharp edges or burrs at contacts with the conductors; and should be of a size proportionate to the size of the line conductor.



SEE TABLE FOR DISTANCE FROM POLE
LOG
INSTALLATION OF LOG ANCHOR

30' & 40'	15 FT.
45' & 50'	20 FT.
55' & 60'	25 FT.

FIG. 18.

B. Copper line conductors should be tied with annealed copper ties; aluminum conductors should be tied with aluminum tie wires only, and before tying the conductor must be wrapped with aluminum armor wire. For details of the copper ties, see Section 11, Overhead Systems Reference Book.

Lightning Arresters

A. In localities subject to frequent lightning disturbances, the installation of lightning arresters will materially reduce the blowing of fuses at transform-

ers and will also give limited protection against injury to the transformers. No definite recommendation as to the installation of lightning arresters can be given, except that they should be placed on the same pole with the equipment they are to protect. Experience is the chief factor in determining where and when to install arresters.

Branch Line Cutouts

A. Branches may be connected to the main line through fused cutouts to facilitate main line operation. Fuses should not be installed in the cutout for the neutral or grounded conductor of the primary. No definite recommendations can be made regarding the size of fuse, as conditions vary greatly; the size fuse to be used is largely a matter of experience.

Grounding

A. Grounds should be installed on all lightning arresters, on the cases of all the transformers mounted on the ground or mounted on steel framework; and on the neutrals of secondaries of all transformers operating at a potential of 230 volts or less, except that they may be omitted in the case of transformer banks for strictly power purposes.

B. Lightning arresters should not make use of the same ground connection which serves for the secondary except where a grounded common neutral system is used.

C. Grounding wires should have a conductivity at least equal to that of No. 6 A. W. G. copper and should be protected from mechanical injury for a distance of at least 8 ft. above the ground with wood molding or its equivalent.

D. The ground resistance should preferably be not more than 3 ohms for water pipes and 25 ohms for artificial or driven grounds. Driven or artificial grounds, particularly in light dry soil, may be uncertain, and consequently efforts should always be made to have the rod or pipe extend far enough into the earth to reach permanently moist soil. If the ground resistance is too high, it may be lowered by the installation of additional rods or pipes, or by the use of zinc chloride or salt, a solution of which is used to saturate the earth around the ground rod and additional quantities of the salt periodically placed in a hollow dug in the earth around the rod near the top.

E. For further information on the subject of protective grounding methods, refer to Section 9 of Handbook No. 3 of the Bureau of Standards, Fourth Edition of the National Electrical Safety Code.

Transformer Installations

A. A method of mounting transformers is shown in the following drawing. For further information refer to Section 11, Overhead Systems Reference Book.

B. In making transformer installations, particular care should be exercised to provide supports strong enough to keep the transformer in position and to so locate the transformer, its fuses and wiring, that the installation will be accessible, safe to work on and will present a neat appearance.

C. Transformers should be mounted high enough so that no live parts shall be less than 15 ft. from the ground, except that large transformers may be mounted lower than this, provided the location permits building a protective fence at least 8 ft. high.

D. Primary leads should be brought down the pole in such a manner as to properly clear all other wires and attachments and to leave ample room for working safely on the pole.

E. Fuse boxes or cutouts should be mounted on the side of the crossarm or pole opposite the transformer, should be so located that they can be pulled from below, and should also be so located as to keep the climbing space clear.

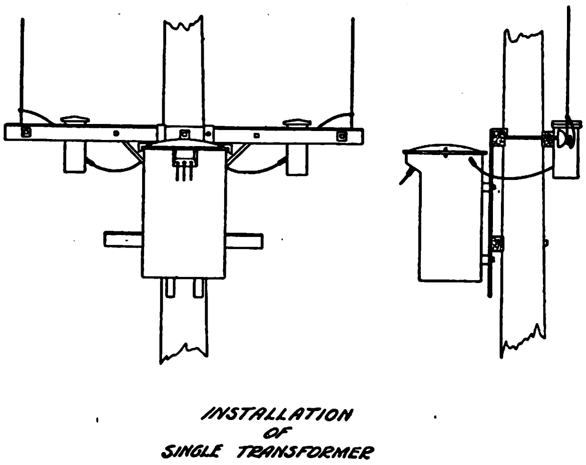

FIG. 21.

F. Lightning arresters to protect the transformer installation should be mounted on the crossarm with the transformer, if practicable.

Services

A. In order to provide capacity for future growth of load and also to reduce voltage drop in the secondary, service and entrance, it is strongly urged that three-wire entrances for 115/230 volts be installed for all service connections, and that service wires be preferably not less than No. 8 A. W. G.

Economical Use and Spacing of Rural Line Transformers

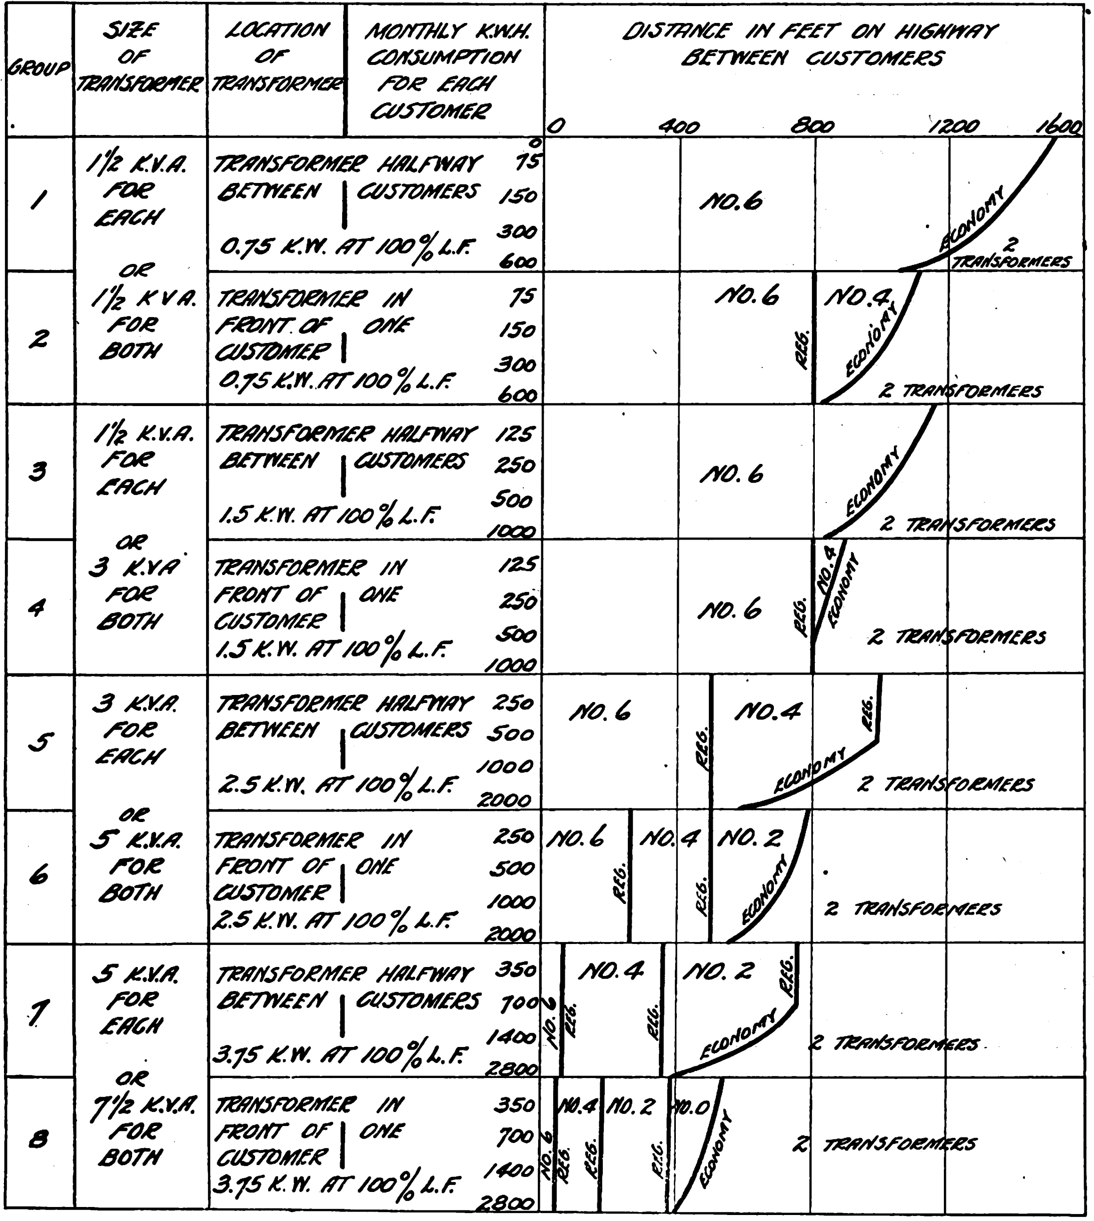
A. Following is a discussion of the economy of extending secondaries versus installing additional transformers on rural lines. The return, fixed charges and cost figures quoted are intended to be illustrative only. It should be understood that such figures cannot be representative of costs generally, for all territories and local conditions, or for all present or future dates. In individual instances the operating company concerned can substitute its own actual costs, and therefrom draw conclusions which will apply accurately to its own conditions.

B. Fig. 22 and 23 and instructions given below cover the above subject and have been drawn up primarily for use in the field. With the data at hand, additional typical problems can be added if desired.

ECONOMICAL USE & LOCATION OF RURAL TRANSFORMERS

THE 3% LIMIT OF REGULATION USED IS THAT ON THE LOADED SIDE OF A 3 WIRE SECONDARY WITH CURRENT IN ONE OUTSIDE WIRE EQUAL TO FULL LOAD ON THE SIZE TRANSFORMER NECESSARY TO SERVE CUSTOMER SEPARATELY, WITH 30% CURRENT IN NEUTRAL AND 70% CURRENT IN OTHER OUTSIDE WIRE WITH LOAD AT 80% POWER FACTOR. ON THIS BASIS IT IS ASSUMED THAT THE WINTER PEAK LOAD MIGHT OVERLOAD TRANSFORMER 50% FOR SHORT INTERVALS GIVING 4.5% SECONDARY REGULATION AS A MAXIMUM. IT IS ASSUMED, THEREFORE, THAT THE SELECTION OF TRANSFORMER SIZE WILL BE GOVERNED ACCORDINGLY. TO GAIN HIGHEST ECONOMY AND ALSO TO KEEP THE VOLTAGE REGULATION IN SECONDARY AND SERVICE WITHIN 3%, THE FOLLOWING SIZE OF WIRE IS REQUIRED.

ASSUME EACH CUSTOMER HAS A 115-230 VOLT, 3 WIRE SERVICE.



GROUP	SIZE OF TRANSFORMER	LOCATION OF TRANSFORMER	MONTHLY K.W.H. CONSUMPTION FOR EACH CUSTOMER	DISTANCE IN FEET ON HIGHWAY BETWEEN CUSTOMERS 0 400 800 1200 1600

FIG. 23.

C. In working up these charts the following factors have been taken into account:

1. Return and fixed charges on investment.
2. Transformer core losses at 2.5 cents per kw-hr.
3. Transformer and secondary copper losses at 2.5 cents per kw-hr.
4. Estimated kw-hr. consumption.
5. Voltage regulation.

D. Return and fixed charges have been assumed as follows:

	Per Cent
1. Depreciation of transformers and arresters	3.00
2. Depreciation of other equipment	2.32
Note: Depreciation is on the 4% sinking fund basis.	
3. Taxes and insurance	2.00
4. Maintenance on transformers and arresters	5.00
5. Maintenance on other equipment	3.00
6. Return	7.00

E. Material and labor costs have been figured as follows:

(1) *Two Transformer Installations Exclusive of Guying*

	Size	Quantity	Approx. Cost per Unit	Cost
Crossarm—4 pin	3½" x 4½" x 5'-7"	4	$0.73	$2.92
Braces	¼" x 1¼" x 28"	8	.10	.80
Machine bolts	⅝" x 16"	2	.09	.18
Spacing bolts	⅝" x 16"	4	.13	.52
Carriage bolts	⅜" x 4½"	8	.02	.16
Square washers	2¼" x 2¼" x ¼"	20	.016	.32
Lag screws	½" x 4"	8	.03	.24
Pins—locust	1½" x 9"	16	.04	.64
Insulators		9	.10	.90
Wire—weatherp'f	No. 6—60 ft.	6.72 lb.	.17	1.15
Transformer	6900-230/115 volts, 3 kv-a.	1	64.83	64.83
Lightning arrester	7500 volts	2	18.25	36.50
Fuse switch	7500 volts	2	8.75	17.50
Ground point, cap, rod, molding		2	1.50	3.00
Solder, tape, etc.				.75
Total				$130.41
Stores department charges, 10%				13.04
Labor				25.00
Total				$168.45
General office sup., 10%				16.84
Total estimated cost				$185.29
Cost of two transformer installations				$370.58

(2) *One Transformer Installation, Exclusive of Guying*

Total of 3 kv-a. transformer installations	$130.41
Minus cost of 3 kv-a. transformer	64.83
Total	$65.58
Plus cost of 5 kv-a. transformer	79.40
Total	$144.98
Stores department charges, 10%	14.50
Labor	25.00
Total	$184.48
General office sup., 10%	18.45
Total estimated cost	$202.93

(3) *A Guy at Each End of Secondary Lead*

	Size	Quantity	Approx. Cost per Unit	Cost
Anchor rods	¾" x 6'	2	$1.17	$2.34
Anchors, cone	8"	2	.70	1.40
Lag screws	½" x 4"	4	.03	.12
Guy hooks	4" x ⅜" x 1¾"	4	.075	.30
Strain plates	14 gage	2	.072	.144
3-bolt clamps	6"	12	.205	2.460
Guy thimbles	½"	2	.048	.096
Guy wire protector	8'	2	1.650	3.300
Guy wire	⅜"	100 ft.	18.10M	1.810
Strain insulator		2	.350	.700
Total				$12.67
Stores department charges, 10%				1.27
Labor				10.00
Total				$23.94
General office sup., 10%				2.39
Total estimated cost				$26.33
Cost of 5 kv-a. transformer installation				202.93
Total				$229.26
Minus one single crossarm in place				1.85
Total cost of fixed equipment				$227.41

(4) *Variable Equipment on Secondary Run*

Investment in one 150 ft. span of 3 No. 6 T. B. W. P. conductors:

	Size	Quantity	Approx. Cost per Unit	Cost
Crossarm—4 pin	3½" x 4½" x 5'-7"	1	$0.73	$0.73
Braces	¼" x 1¼" x 28"	2	.10	.20
Machine bolt	⅝" x 12"	1	.07	.07
Carriage bolts	⅜" x 4½"	2	.02	.04
Square washers	2¼" x 2¼" x ¼"	2	.016	.032
Lag screw	½" x 4"	1	.03	.03
Pins—locust	1½" x 9"	4	.04	.16
Insulators		3	.10	.30
Wire, weatherp'f	No. 6	52 lb.	.17	8.85
Total				$10.41
Stores department charges, 10%				1.04
Labor				4.25
Total				$15.70
General office sup., 10%				1.57
Cost of secondary per span, total				$17.27

F. Transformer costs and losses have been assumed as follows:

2300 *Volt*

Size	Approx. Cost	Core Loss at 115 Volts	Copper Loss at Full Load
1½ kv-a.	$30.00	21.5 watts	43 watts
3 kv-a.	43.00	32 watts	75 watts
5 kv-a.	58.00	40 watts	99 watts
7½ kv-a.	75.00	54 watts	126 watts

6900 *Volt*

1½ kv-a.	$53.00	27 watts	55 watts
3 kv-a.	65.00	36 watts	87 watts
5 kv-a.	80.00	50 watts	170 watts
7½ kv-a.	100.00	69 watts	200 watts

Core losses were increased by 10 per cent for customary farm line voltages.

G. Assuming that a customer uses a certain number of kw-hr. per month, the copper losses were figured on the assumption that this amount of energy was used at the rate of one-half load on the size of transformer required to serve the customer individually. This probably gives results nearer to the actual copper losses than would be obtained under any other method.

H. The estimated kw-hr. is considered only because of its influence on copper loss.

I. For any particular set of conditions there is a certain relation between primary, transformer, secondary and house wiring drop that gives the highest overall efficiency and lowest annual costs. It is with this point in mind that 3 per cent regulation has been allowed for the secondary and service in working up the results shown on the attached sheets. Allowing 8 per cent regulation at the customer's cutout leaves 5 per cent for primary and transformer drop.

The 3 per cent limit of regulation allowed for secondary and service drop is that on the loaded side of a three-wire secondary with current in one outside wire equal to full load on the size transformer necessary to serve customer separately, with 30 per cent current in neutral and 70 per cent current in other outside wire with load at 80 per cent power factor. On this basis it is assumed that the winter peak load might overload the transformer 50 per cent for short intervals, giving 4.5 per cent secondary regulation between the transformer and the customer's service entrance as a maximum. It is assumed, therefore, that the selection of transformer size will be governed accordingly.

J. In general the problem is to decide whether two rural customers should be served from one or from two separate transformers. If they are served separately, each may require a certain size of transformer. However, if served jointly, the size of transformer required may not be equal to the sum of the individual requirements. After taking into consideration the type and size of farm to be served, together with the means and desires of the prospective customers, probable future connected load and the best size of transformer can be determined. In the following charts the column headed "Size of Transformer" covers nearly all the combinations that might arise. For example, groups (1) and (2) cover the condition where the combined load could be served from a 1½ kv-a. transformer. Groups (3) and (4) represent the condition where each would require separately 1½ kv-a., but 1½ kv-a. would be too small for their combined load. Other similar cases are also shown.

For each one of these combinations of transformer size, there are several probable locations for the transformer. One of the customers may be getting service and may already have a transformer installed in front of his place; or neither one may be getting service at present, and it will then be possible to install the transformer wherever it may best be placed. The next column on the charts, headed "Location of Transformers," is designed to cover those two situations. For the sake of simplicity, it has been assumed in all cases that the primary line for other reasons extends in each direction beyond each customer under consideration, that each customer's service entrance is 300 ft. back from the primary line, and that both secondaries and services are three wire and of the same size wire. It has also been assumed that the transformers are always placed on the highway and not back on the customer's premises.

The next item to be considered is the monthly consumption. This is shown in the next column on the chart, and is assumed to be the same for each customer. The kw-hr. consumption affects only the cost of copper losses in transformers and secondaries.

The next variable item is the distance between customers measured along the primary line. This does not include the 300 ft. service drop for each customer, nor does it depend upon the number of wires considered. This distance is 600 ft. less than the distance between the two customers' service entrance switches measured along the secondary lead. The distance measured along the highway (primary line) between customers is plotted as ordinates across the top of the chart.

The only physical item left is the size of the wire required. With the conditions as already given, there are only two factors left which can determine the size of wire; these are economy and voltage regulation. Mechanical strength limits the size to number 6 A. W. G. or larger. The wire size is shown in the body of the chart.

Assume the conditions which are fixed are as given under Group 5. A 3 kv-a. transformer could serve each customer separately; 5 kv-a. will be required to serve the combined load, and neither is being served at present. If only one transformer is used, it can be placed halfway between them. By reference to the chart, it can be seen that, if the distance between customers measured along the highway (primary lead) does not exceed 500 ft., No. 6 wire will be adequate regardless of the amount of energy consumed. However, if this distance exceeds 500 ft. and is less than 1000 ft., and the estimated consumption per customer is 450 kw-hr. or less per month, No. 4 wire will be required. If the estimated consumption should exceed 450 kw-hr. per month for each customer and not exceed 750, No. 4 could be used up to distances between customers not exceeding 900 ft. Also, if the estimated consumption should exceed 750 kw-hr. per month for each customer, No. 4 wire could be used up to distances between customers not exceeding 600 ft. For distances greater than these, qualified by the estimated consumptions, two transformers should be used.

The vertical lines marked "Reg." dividing the areas indicate that voltage regulation is the determining factor in limiting the distance to which service can be supplied from one transformer. The curved lines marked "Economy" dividing the areas indicate that a balance between losses and fixed charges determines the limiting distance.

The following problems and their discussion show the use to which the charts may be put:

PROBLEM No. 1

A rural customer desires service and another customer nearby has a transformer in front of his residence. In this case the problem involved is to determine whether the present transformer should be replaced by a larger one and secondary extended, or whether a new transformer should be hung for the prospective customer.

Assume that the primary voltage is 6900; that 1½ kv-a. would adequately serve the prospective customer, that the present transformer is a 1½ kv-a. and that it would require a 3 kv-a. to serve both. Also assume that each customer's service would be about 300 ft. long and that the distance between the service drops measured along the primary is 900 ft.

Assuming that each customer might use 80 kw-hr. per month, the most economical procedure, according to Group 12 on the chart, is to replace the 1½ kv-a. with a 3 kv-a. unit, and extend a No. 4 three-wire secondary to the prospective customer. If the distance had been 1200 ft., it would have been more economical to hang separate transformers, for even if an attempt had been made to relocate the original transformer halfway between the customers to take advantage of the greater distance allowed in Group 11 on the chart, the charges resulting from moving the protective and auxiliary equipment would have overbalanced the leeway of 350 ft., shown in Group 11 on the chart.

PROBLEM No. 2

Assume two prospective customers are 800 ft. apart on a 2300 volt primary. One requires a 5 kv-a. and will use 300 kw-hr. per month; the other requires a 1½ kv-a. and will use 80 kw-hr. per month. Assume each has a service drop of 300 ft. of the same size wire as that to be used in the secondary.

Although the consumption influences the results only slightly, it is considered only to show just what influence it has. The size and length of service drops alter the results only by virtue of the effect upon voltage regulation and do not affect the balance of economy involved.

If it is eventually found that these customers should be served on one transformer the logical location for the transformer is such that the distances to the customers exclusive of service drop are inversely proportional to the respective demands, provided the secondary wire size is the same to each customer. Therefore, the distance from the transformer to the smaller customer would be:

$$\frac{5}{5 + 1.5} \times 800 \text{ ft.} = 615 \text{ ft.}$$

This leaves 185 ft. from the transformer to the larger customer.

Since this type of problem has not been placed on the chart, the next best thing is to pick out two or three cases treated on the chart which hit on either side of the conditions desired, and draw conclusions therefrom.

As far as the smaller customer is concerned, it can be assumed, in using the chart, that the conditions on the other side of the transformer are equal to his. This is equivalent to the case where the customers are 2 × 615 or 1230 ft. apart. Group 1 on the chart indicates that No. 6 copper secondary could be used for the smaller customer. Group 2 indicates that separate transformers should be hung, not because of regulation, but because of overall economy.

As far as the larger customer is concerned, it can be assumed also in using the chart that the conditions on the other side of the transformer are similar to his. This is equivalent to the case where the customers are 2 × 185 or 370 ft. apart. Group 7 on the chart indicates that No. 2 secondary could be used for the larger customer.

Although one indication points toward the use of two transformers, two indications favor the use of only one transformer. The best probable procedure, according to the assumptions made, would be to use one transformer, place it approximately 185 ft. from the larger customer and build No. 2 and No. 6 secondaries to the larger and smaller customers respectively. However, this conclusion was based on assumptions which included the logical location of the transformer provided the secondary wire sizes were the same to each customer. Such is not the case with the final decision, and the difference in conductivity of the two sizes of wire must be taken into account.

In the new problem the size and length of service drops alter the results by virtue of the effect upon voltage regulation, but do not affect the balance of the economy involved. If it is eventually found that these customers should be served on one transformer, the logical location for the transformer to give the same voltage regulation to each is such that the distances to the customers, including service drop, are inversely proportional to the respective demands, when consideration is also given to the fact that No. 2 wire has about 2.55 times the capacity of No. 6 wire. Therefore, the distance from the transformer to the smaller customer would be:

$$\frac{5 \times 800 + 5 \times 300 - 1.5 \times 2.55 \times 300}{1.5 \times 2.55 + 5}$$

which equals 495 ft. This leaves 305 ft. to the larger customer.

As far as the smaller customer is concerned, it can be assumed, in using the chart that the conditions on the other side of the transformer are equal to his. This is equivalent to the case where the customers are 2 × 495 or 990 ft. apart. Group I on the chart indicates that the No. 6 copper secondary could be used for the small customer. Group 3 indicates the same result.

As far as the larger customer is concerned, it can be assumed also in using the chart that the conditions on the other side of the transformer are similar to his. This is equivalent to the case where the customers are 2 × 305 or 610 ft. apart. Group 7 on the chart indicates that No. 2 secondary could be used for the larger customer.

All three indications point toward the use of one transformer. The best probable procedure, therefore, would be to use one transformer, place it approximately 305 ft. from the larger customer and string No. 2 and No. 6 secondaries to the larger and smaller customers respectively.

PROBLEM No. 3

Assume that it is desired to obtain from this chart information as to how far a three-wire, 115/230 volt secondary can be run from an urban transformer to a customer. Assume the customer's load is such that, if he were being served on a separate transformer, a 3 kv-a., 2300 volt would be required, and assume that his consumption is 300 kw-hr. per month. He falls in Group 6.

According to the agreed division of voltage drop between primary, secondary and service, the following restrictions are read from the chart. In each case we assume that the customer's cutout is 2 spans from the highway, and that the same sized wire is used throughout from the transformer to the cutout.

Distance in feet on highway in addition to the 2 spans of service drop	Size of Wire	Factor determining upper limit of distance
0 to 250 ft.	No. 6	Regulation
250 to 500 ft.	No. 4	Regulation
500 to 760 ft.	No. 2	Economy
Beyond 760 ft.	A separate transformer	

PATROL AND INSPECTION OF TRANSMISSION LINES

The Maintenance Methods and Procedures Subcommittee of the Overhead Systems Committee was appointed to determine the practice of member companies concerning their maintenance methods and procedures, as applied to overhead lines and apparatus.

The subcommittee has been recently engaged in the consideration of the procedures and methods applied in patrolling and inspecting transmission lines.

This Serial Report is based on a résumé of the 105 *replies to a questionnaire sent to member companies in this country and Canada to determine their practice in the patrol and inspection of transmission lines.*

An analysis of the returns by Geographic Divisions is shown in Table I. Table II is an analysis of the returns by systems.

SUMMARY

The information returned by the member companies shows their almost unanimous opinion is that periodic patrolling is worth while from the standpoints of continuity of service, increased revenue and public safety. Any one of these factors alone appears to be sufficient cause for periodic patrolling.

In direct answer to the question, "Do you feel that patrolling of transmission lines is justified?" 104 replied in the affirmative. The other company reports that patrolling is justified only after indications of trouble. One of the 104 companies which said patrolling was justified does not patrol. This is probably due to the limited mileage and special conditions of the system.

The reason given by 95 of the companies for patrolling is that conditions which might cause a line failure and interruption to service are detected and repaired before the damage is done. From the economic standpoint ten companies report an actual increase in revenue as a result of periodic inspection, while seven companies assert that inspecting increases public safety and, therefore, public good will.

While there seems to be a nearly unanimous opinion in favor of patrolling, there are some differences concerning details.

The frequency and manner of patrolling apparently, from the answers returned, depends somewhat on how rigid an inspection is maintained. Other factors which influence these are the size of the system, the voltage and importance of the line, as well as its general condition. The equipment carried and the instructions to patrolmen varies with the work included at the time of patrolling, and whether it is a periodic or an emergency patrol.

DETAILED INFORMATION FROM THE QUESTIONNAIRE

Thirty companies patrol in crews of two or more, while 80 patrol individually. A few companies use both methods, depending on which is the more convenient and economical at the time. It is of interest to note the following:

63 companies report no other work when patrolling.
25 do minor repair work on the lines. (In general repair work is done by those who patrol in crews).
7 repair their own telephone lines.
6 include substation inspection.
2 check readings of the substation meters.
1 tests the street lights.
1 reads meters in secluded districts.
1 estimates the cost of labor and material necessary to repair defects.

TABLE I

ANALYSIS OF RETURNED QUESTIONNAIRES GEOGRAPHICALLY

Geographic Division	Number of Companies Reporting	Number of Systems	Number of Miles of Transmission Lines by System Voltage						Total of Each Division
			11–15	15–30	30–60	60–100	100–150	150–	
1. Canada	3	8	130.90	....	228.00	528.00	396.7	270	1,555.60
2. New England	19	40	760.79	279.99	632.21	676.75	30.00	....	2,379.74
3. Eastern and Middle Atlantic	24	71	1,837.46	3,121.97	2,136.85	3,449.12	1,873.12	227	12,645.52
4. South Eastern, South Western and East Central	22	60	2,378.07	876.86	4,776.46	2,700.14	3,763.17	....	14,494.70

Publication No. 289-42, Serial Report, Overhead Systems Committee.

TABLE II

ANALYSIS OF RETURNED QUESTIONNAIRES BY TRANSMISSION SYSTEMS

Transmission Line Voltage, Kv.	Systems Reported	Mileage
11–15	75	20,719.22 mi.
15–30	54	7,194.18
30–60	64	16,391.12
60–100	57	14,076.72
100–150	41	10,203.88
150–	5	1,473.00
	296	70,060.02 mi. Total

Time Interval Between Patrols

Table III indicates the "Time Interval of Patrolling by Voltages." A number of the companies will appear more than once in this table as they have more than one time schedule.

TABLE III

TIME INTERVAL BETWEEN PATROLLING BY VOLTAGES

Time Interval	Kilovolts					
	11–15	15–30	30–60	60–100	100–150	150–
1 day	1	....	....	....	.....	.....
2 days	1	....	....	....	.....	.....
3 days	2	....	2	1	.....	.....
4 days	....	2	....	....	.....	1
1 week	11	12	13	14	11	3
10 days	2	3	2	1	2	.....
2 weeks	2	9	15	10	9	1
3 weeks	1	2	....	1	1	.....
1 month	17	15	21	19	13	1
2 months	2	3	4	4	1	.....
3 months	....	1	1	1	.....	.....
6 months	2	2	....	....	1	.....
1 year	....	....	....	1	.....	.....

Two of the companies patrol only after indication of trouble on the line, such as breaker operation. Several patrol after every storm as well as periodically, whether there is indication of trouble or not. In a few cases on parts of systems, the period is varied or adjusted so that patrolling takes place after storms only.

Patrolmen Living Along Lines

There are five companies whose patrolmen live along the lines. Only one of these forwards any detailed information on the subject. An extract from this company's instructions follows:

> In general patrolmen will live in quarters made available by the company. Telephone service will be provided at each of the living quarters.
>
> All patrolmen are required to be on duty during working hours on all days other than Sundays and holidays. Absent time allowances, vacations, etc., will be allowed in accordance with the rules and regulations of the company. All absences from duty must receive the sanction of the superintendent and be carried out with due notification to and with the knowledge of the work despatcher.
>
> On alternate evening the patrolmen will be expected to hold themselves available for call.
>
> Each patrolman will be required to patrol the entire section assigned to him once every week. Patrolmen will be required to climb and make a detailed inspection of each tower at least once every month.
>
> In climbing towers two patrolmen will work together, climbing alternate towers independently. This regulation is put into effect in case of an accident to one man, there will be another man in the immediate vicinity available to render assistance. Where possible, patrolmen on adjacent sections will assist each other in the inspection, under the direction of the work despatcher. Where this is unpracticable another man from the maintenance gang will assist.
>
> In all cases of unusual weather conditions, such as snow storms, ice storms, thunder storms, wind storms, extremely hot or cold weather, hurricanes, earthquakes, etc., all previous arrangements and schedules for release are automatically cancelled.
>
> The patrolmen are required, as soon as such conditions become evident, to immediately report over the nearest telephone to the work despatcher or supervisor. From that time on until conditions are relieved, patrolmen will, at all times, keep the work despatcher informed as to their location or destination.
>
> During the time the patrolman is making his inspection he will be expected to take care of any small jobs requiring attention which do not require any special tools—such as tightening up loose bolts, temporarily fixing fences, putting in bars, etc.
>
> In case of finding any major defects on the line—such as broken strands in the conductors, shattered or burnt insulators, burnt guard rings or hardware, burnt conductor, presence of kites or other foreign obstacles on the wires—he shall immediately call and report to the work despatcher.

Transportation

An analysis of the method of transportation is given in Table IV.

TABLE IV

System Voltage (Kv.)	Foot	Horseback	Automobile	Trolley, Train and Speeder	
11–15	5,531.22	54.5	3,146.6	30	Total mileage reported in answer to this question.
15–30	4,902.94	44.0	2,780.9	21	
30–60	8,733.82	1,283.0	2,926.0	692	
60–100	8,461.92	259.3	3,146.6	?	
100–150	7,131.18	365.0	124.0	?	
150–	393.0	124.0	751.0	?	
	35,154.1 mi.	2,129.8 mi.	12,875.2 mi.	743	*50,902.1

---

*This does not show the total system mileage reported because of insufficient information but is accurate enough to give an idea of the general practice of the country.

Table V shows the miles in the different systems that follow private rights-of-way, highways and streets. Nearly all lines on rights-of-ways are patrolled on foot. Thirty per cent of those on streets or highways are patrolled this way as well.

Special Equipment

Of the 105 companies reporting

57 use field glasses on patrol,
8 use pole butt testers,
5* use hot line tools,
4 use telephone test sets,
4* use insulator testing equipment,
2 use radio trouble finders.

---

*These companies patrol in crews.

Two companies state definitely that their patrolmen do not use field glasses. In response to a letter from the committee, one company says:

> Some years ago the patrolmen were supplied quite generally with field glasses for use in patrolling and inspecting lines. However, the experience obtained during such procedure convinced us that proper patrols were not being made, but that the men were taking the easiest method—using field glasses to inspect their lines. Generally, glasses are valuable in locating trouble. Occasionally, by the use of the glass, the man will pass up trouble, thereby increasing the length of the outage; also the expense to find and repair the trouble.
>
> After considerable experience where the glasses were used, all equipment of this sort was called in and instructions issued that patrols must be made directly under the line. Since this procedure has been established, the operating record of the transmission lines has improved quite materially, less failures have resulted and there have been very few cases of trouble which have been passed. For the above reasons we feel that the use of field glasses by our patrolmen is not practical.

TABLE V

System Voltage (Kv.)	Private Right of Ways	Highways and Streets	Total
11–15	6,136.94	13,373.12	19,510.06
15–30	3,471.68	3,346.32	6,818.00
30–60	12,215.02	3,846.49	16,061.51
60–100	8,256.38	4,183.44	12,439.82
100–150	7,679.76	1,997.63	9,677.39
150–	1,370.00	103.00	1,473.00
	59.3%	40.7%	65,979.78

Another company answers as follows:

> No special equipment is used. I have tried field glasses on various occasions, particularly for spotting burns or defects in the cables, but have always found that the bare eye will detect such defects much easier than can be done with the help of field glasses. The reason for this seems to be that the background is always the sky, and no matter if the sky is clear or cloudy, the cable seems to blend with the background so that it practically disappears when looking through the glasses.

One company reports using a camera, another having the patrolmen carry snake bite treatment, another a slack puller, and a fourth wading pants. The transportation equipment generally used is of the lighter type of car, in most cases Fords, Dodges, Chevrolets, etc.

MEMBER COMPANY PRACTICE

The following has been extracted from letters written by two companies when answering the questionnaire, which are of more than ordinary interest.

APPALACHIAN ELECTRIC POWER COMPANY

> In the past the various lines have been patrolled on foot, once or twice a year, or as often as the local manager deemed desirable. If a line was giving more or less trouble, it accordingly received more patrolling.
>
> We are this year inaugurating a new system of general inspection patrol to be made spring and fall, just after the lightning season, and the results obtained from this patrol will determine just about how often it will be necessary to make general inspections over our entire system in the future.
>
> This general inspection patrol is copied after the system that I have been using for a final inspection of all of our transmission lines during and at the end of construction, before they are turned over to the operating department. I have been keeping a regular form of inspection report for several years, which is now being made the basis of our general patrol report, of which I am inclosing several blank copies.
>
> This inspection crew is made up of three, four or five men, who work together under a chief inspector. They climb every structure and make a detailed examination as close to the conductors as possible. They examine all bolts on their way down the structure, tightening any that might be loose, and report any condition that they find is not normal. We note on this report various specific points that must be covered during the inspection, so that they will not be overlooked. Under the question of clearance, they measure the actual clearance if the line is not alive, and where lines are alive they note "good" or "poor," as the case might be. All of our structures are numbered, and a separate sheet is made out for each individual structure. A copy of this report is sent to the general superintendent, and a copy furnished to the system operator and to the operating district managers. If the report indicates that repairs are necessary, the district manager arranges, at the present time, to make the necessary repairs when the lines can be taken out of service, after which a re-inspection is made and additional reports filed with the respective parties.
>
> We keep in our office a record of all of these reports, by structure number, so that if anything happened on any particular structure, we could tell how often and when it had been inspected.

EASTERN CONNECTICUT POWER COMPANY

> Originally we had regular patrolmen patrolling our transmission lines and found the work both expensive and unsatisfactory, due to repeated misses or overlooking of defective conditions. Under this scheme the patrolling of the line was of doubtful value and very unsatisfactory.
>
> We have now adopted a scheme of having the patrolling done by a crew of four, taken out of the regular line department. These men, being the ones who would naturally have to repair defective lines after trouble has occurred, which might well be at very inconvenient times and under very bad weather conditions, have a very definite interest in seeing that the patrol is as thorough as possible.
>
> The method of operation is for a crew of four men with a light truck (usually a Reo Speed Wagon) to start out until they reach the nearest point on the transmission line to be patrolled. This crew of four is composed of two climbers and two groundmen, who are also competent chauffeurs. At the start of the transmission line, two men, a climber and groundman, start to patrol the line. The other two men take the truck to a designated highway crossing, leave the truck and start to patrol along the line in the same direction that the original two started. When the first two come to the crossing where the truck is, they take the truck and drive to another point further along the line, and the procedure is repeated. In this way we are able to patrol a line in a very economical manner with men who are very definitely interested in seeing that the patrol is most thorough, and the results have been very satisfactory.
>
> It is our practice to patrol the 66-kv. lines at least once a month at all seasons of the year with this method, and the lower voltage lines with the same frequency in the summer months; but during the winter months, if the weather conditions have been mild, we sometimes extend the time to eight weeks. Regardless of this systematic patrol if, at any time, the lines go out either during a thunder storm or any other time, unless the cause of the interruption is definitely known, an additional patrol is made; and, in addition, during the severe lightning season patrols will be made even though the line in question had no interruption during the preceding storm.
>
> We have found this method of handling the work both economical and very satisfactory. Our experience with regular patrolmen who do no other type of work was extremely unsatisfactory, both in the expense of the work and in the reliability.

INSTRUCTIONS

Several companies inclosed supplements in answer to the request for additional information. An attempt has been made to pick out the more representative types of instructions for patrolmen, and, it is hoped that these, together with some representative report forms that have been selected, will present a general idea of what the patrolmen are instructed to do and observe. The selections from the sets of instructions received follow.

KANSAS GAS & ELECTRIC COMPANY

Most men make the mistake of regarding patrolling as a simple, easy job which anyone can do, provided he can walk. A good patrolman must have the same characteristics which insure success in other work, i.e., he must concentrate on the task at hand, must know just what is expected of him and must not only be able to do it but to tell others how it was done. In other words, he must make complete reports correctly portraying conditions.

Patrolmen frequently come in contact with the public. At such times a patrolman should remember that he *is* the company in the eyes of persons he meets and talks to. He should be uniformly courteous and should make every effort to avoid damage to growing crops by reason of his patrolling. By closing all gates he opens, preventing stock from straying, he will build good will for himself and the company.

A patrolman should make the acquaintance of residents along the lines he patrols. He should tell them why patrolling is necessary and something of the importance of uninterrupted service on the lines. Many persons with this knowledge will take the trouble to report wires down or other line trouble when they see or hear of it.

What to Report

All patrolmen at various times are confronted with the question, "Shall I report this?" or "Is this serious enough to report?" A brief review of the reasons for having patrolmen will forever settle this recurring question. There are few cases in which a patrolman can make actual repairs. It necessarily follows that the primary function of a patrolman is to *see* everything and report what he sees. Therefore, a good slogan is: When in doubt make a report.

Patrolmen will report *all* irregularities on both power and telephone lines and stations. Loose tie wires, nuts, clamps, broken insulators, poles and cross-arms; poles out of line, brush into or near lines, etc. Special attention should be given the latter, as service depends on keeping both power and telephone lines clear.

Following are listed a few of the conditions which should occasion a report. You will think of many others as you cover the line.

1. Broken or cracked insulators
2. Poles broken off
3. Poles leaning out of line at the top, 2 ft. or more
4. Broken strands in conductors
5. Broken ground wires
6. Ground wire loose from support
7. Tie wires broken or burned
8. Cross-arm split or rotted
9. Nuts off or loose on any poles
10. Broken or slack guys
11. Trees or tree limbs in such positions that they may touch or blow into the line wires or telephone wires. Any trees which, if they broke off at the ground line, would fall into the wires are considered danger timber and should be reported
12. Trees under the line with clearance of less than 4 ft.
13. Trees clearing the telephone line less than 2 ft. underneath or 4 ft. to one side
14. Broken guy insulators
15. Broken telephone insulators
16. Woodpecker holes that impair the strength of the pole. If you are unable to tell the extent of such holes, report this fact and a special inspection will be arranged for.

You will report all dangerous conditions each time that you cover the line until the condition is corrected, unless special permission is granted by the general foreman to cease reporting individual troubles.

If lines are not in need of repairs, the reports should so state. Reports requiring immediate attention telephone to the despatcher. Less important reports will be noted on the patrolman's daily report (Form No. 1276) which will be mailed to the patrol headquarters daily. Reports telephoned to the despatcher will be noted on the daily report with the time of telephoning, person receiving the report, etc.

Patrolmen will report in the morning the route they expect to cover, will call in over private line at each phone station, and will report as soon as they have covered the section of line assigned for the day.

Patrolmen walking lines on which no company telephones are available will report on public telephone and maintain a reporting schedule where possible, as follows:

Morning, mid-morning, noon, mid-afternoon and night.

The Neosho-Midian line is an exception to this rule. When patrolling this line reports will be made to the nearest despatcher (Wichita or Neosho) morning and night. No other reports will be made unless trouble requiring immediate action is involved.

Patrolmen will report promptly the approach of a storm and will give the telephone number at which they can be called during the progress of the storm. If the storm is general in character or progresses along the line the patrolman should again report to headquarters before he resumes patrolling. This instruction applies to all lines.

Repetition of Reports

The question frequently arises whether to report a condition once or to report the same condition on each inspection trip until it is corrected. A report once having been made, should be repeated on the subsequent trips until the repair work is done or until the patrolman has been authorized to cease making the report. Such permission will be for the case at hand only, and should not be construed to apply to other reports.

General Instructions for Emergency Patrolling

The importance of efficient organization for emergency patrolling is shown by the fact that locating trouble on lines often takes longer than repairing the break after it is located. Since communication with patrolmen is lost when they start, it is of great importance that each man understands what to do in emergencies. The following general instructions should be followed. They will be supplemented by special instructions to cover extraordinary features of the case at hand.

1. Stay away from the line. You do not have clearance on it, and it may be energized or tried out at any time.
2. Walk from your starting point in the direction specified until you find the trouble or meet the man walking toward you.
3. Report to system operator (special instructions may require report to someone else) at half hourly intervals if you can do so without getting so far away from the line as to risk not seeing another patrolman. If you are on a cross-country line and do not pass telephones, make a big effort to telephone your headquarters at least once each hour.
4. When you locate the trouble go to the nearest telephone and report, making sure that you give exact location and as nearly as possible the extent of the damage. If you are not given specific instructions at this time, return to the breakdown and guard the public and domestic animals from accident. After you locate the trouble and report it you can usually do a lot, even if you are alone, to speed the repairs.

When you talk to the system operator, therefore, get clearance on the line, ***provided you are not ordered to leave the location,*** and do all you can. The system operator will ordinarily have the line opened and will be ready to issue clearance on it by the time the location of the trouble is reported to him. If you are in doubt as to what you alone can do to repair the damage while waiting for help, do not hesitate to ask for detailed instructions from headquarters.

5. If it becomes necessary for you to leave the line while patrolling to telephone, leave a note attached to a conspicuous part of the nearest pole or tower, telling where you are and what time you left the line. This will prevent any possibility of another patrolman passing during your absences. Hold order tags are handy for this purpose, and a supply will be kept at crew headquarters for your convenience.
6. If you meet your man or reach the end of the line without finding the trouble, report to the system operator from the nearest telephone and ask for further instructions.
7. Remember that trouble apparently on a line may actually be on substations connected to the line. This is a strong possibility when unattended substations are involved. Be sure, therefore, that you inspect any substation on your section of the line, whether it be at the point from which you start patrolling, end patrolling, or along the line. Exceptions to this will be given as special instructions when necessary.

THE CONNECTICUT LIGHT & POWER COMPANY

Condition of poles, towers, fixtures, guys, anchors, pins, conductors, insulators, lightning arresters, grounds, line transformers and accessory equipment as well as clearances from trees and other obstacles shall be noted. Transmission patrolmen shall pay particular attention to locating cracked or broken insulators, indications of flashover and such trees and limbs as are likely to come in contact with or dangerously close to wires during high winds or when heavily loaded with ice.

At substations, condition of transformers, grounds on transformers and framework, leads, bushings, switches, buses, potheads, cables and accessory equipment, also transformer oil levels and temperatures shall be noted. Attention should be paid to see that buildings furnish proper protection to indoor equipment. Necessity for safeguards, danger or caution signs to warn unauthorized persons of hazards shall be noted.

In the discharge of their duties patrolmen shall not place themselves in hazardous positions, and they shall exercise care not to break or cut down fences or in any way injure crops or property through or over which they must pass.

METROPOLITAN EDISON COMPANY

Make a report of line, or section of line patrolled on transmission line inspection sheet furnished for that purpose.

Report all trouble, or dangerous conditions, by pole or tower number, and the number of line. Give exact location as near as possible.

Always patrol lines directly under the line. (Under no circumstances shall any patrolman go off the right of way to go around a creek or any other obstacle, without coming back to the line as near as possible to the point of leaving.)

Always stop on the *far* and *near* side of all poles, towers and structures and give all equipment a very careful inspection. This is very important on dead-end construction, as some towers have 216 insulators as part of the equipment that *must* be inspected.

Report All Broken Insulators

When a broken insulator is found, make a thorough examination of the ground around the pole or structure, as well as the equipment, and try to determine the cause.

In most cases of broken insulators that have caused line trouble, or have been broken by a power arc, the pieces found on the ground will have the glazing blistered. Insulators broken by stones, or causes other than power arc, will be broken clean.

Examine the Pieces of Insulators Found on the Ground

Report all foreign objects, on any part of conductors, poles, structures or equipment, kite strings, small pieces of wire, limbs hanging over conductors, corn husk, small limbs, paper or any foreign object hanging over the insulators. Loose bark on poles that is likely to swing into line.

Report truss pins leaning, loose tie wires, cross-arms that are loose and standing away from pole, crooked cross-arms, loose through bolts and lag screws, poles leaning out of line, poles and towers that require back-filling, caused by washout or earth settling around base of towers, or butt of poles, loose bolts and tower members, tower members that are bent and out of position.

Report slack guy wires, rusted and broken guys, broken guy strain insulators, trees that are close to, or in danger of blowing into lines.

Report high weeds in structures, switches that are not closed properly, or poorly adjusted, broken switch castings, and switches that are not locked.

A very careful inspection *must* be made at all structures for loose connections and loose lugs.

On several occasions our regular line patrolman has avoided a very serious interruption by finding solder on the ground under switching structures that came out of an overheated lug.

Report all danger signs that have been destroyed or removed from poles, tower and structures.

In no case shall any patrolman hesitate to report any condition that he thinks will cause trouble. The same will be given a very careful investigation.

INSPECTION REPORT FORMS

Fig. 1-6 inclusive are specimen field report forms used by several of the reporting companies.

FIG. 6—(*Left*) TRANSMISSION LINE FIELD INSPECTION REPORT FORM. (*Right*) HIGH TENSION INSPECTION AND REPAIR REPORT FORM—CENTRAL ILLINOIS PUBLIC SERVICE CO.

TYPES OF DISTRIBUTION SYSTEMS, AND METHODS OF EFFECTING CHANGEOVER

Introduction

In the first report of the Electrical Problems of Distribution Subcommittee (Publication No. 267-15), it was stated that the design of distribution systems involved two problems; the first being the development of a system that will serve the connected loads with a high degree of reliability. Very closely related to the first problem is the second one, which is that of economy. A third point to be considered is that of future growth. The design must be so planned that it will be the economical system or will readily grow into such a system under future conditions of load density and reliability requirements.

These points are repeated for emphasis, as it is felt that these are the three guiding principles to be followed in designing any system. The economics should not be slighted and should be the guiding principle in all distribution system design.

A fourth point which in the past has received only slight consideration for residential service, but is becoming more and more important, is that of designing a distribution system so that maintenance and construction can be accomplished with a minimum outage to customers' service. This feature is particularly important in extending an existing system or planning a conversion or revamping of an old one, since a system once installed in accordance with a particular design cannot be altered without a serious number of service outages and considerable expense.

The importance of reducing to an absolute minimum the number of service outages will be readily recognized in view of the number of electrical appliances now being used in the average residence. The increase in the number of oil burning furnaces, electric ranges, electric clocks, washing machines and such equipment makes continuity of service a necessity. Indeed, it is principally through the sale of such equipment that residential consumption of electricity can be increased. Since the continued sale of such equipment depends to a great degree upon the satisfaction obtained in its use, the sale of load building apparatus must not be jeopardized by frequent outages with the resulting discomfort or inconvenience, but should be encouraged by continuous service.

In the first report (Publication No. 267-15) general features of distribution practices were outlined, together with tables showing their relative usage. In this report the study has been restricted to the subject of the design of the individual feeder layout for one general type of system, namely, the 4000 volt, three-phase, four-wire system. It is felt that a general analysis of the various types of feeder layout and the advantages and disadvantages of the various classifications, particularly as to where their application is economical, will be of value. The application of the various types to actual systems is also discussed.

In the second part of this report various methods of changing over to a 4000 volt, three-phase, four-wire system from two-phase and three-phase 2300 volt systems are discussed. As the data in the first report indicated that a number of companies were considering such a changeover, the collection of data regarding the experience and methods followed by other companies in effecting similar changes was justified.

In conducting a changeover of this type the problem becomes partly one of economy. Undoubtedly, in planning a change, various methods of effecting it will be considered, the problem resolving itself into one of choosing the one that will be the most economical and at the same time will not result in a prohibitive number of service outages.

PART I

TYPES OF DISTRIBUTION SYSTEMS

SCOPE

It is the purpose of this report to discuss the various classifications of distribution systems in general, as to their operating advantages, and to present in detail standard types of distribution system connections, especially those used on 4000 volt Star Systems, thus establishing a much needed nomenclature.

The committee has made a survey of 95 companies, studying the distribution systems of 48 of these companies operating a 4000 volt Star System, and has tabulated the following information on the practices and experiences of these companies.

Many companies have reported operation at several different voltages at the present time, due to a transition period, but are gradually eliminating the lower voltages and adopting one or more of the higher voltages as a standard. The reasons set forth by these companies for their change in distribution voltages have been summarized and embodied in this report.

CLASSIFICATION OF VARIOUS SYSTEMS IN USE

The distribution systems of 95 operating companies in the United States and Canada have been classified in Table I as to the range of voltages in use.

Publication No. 289-46, Serial Report, Overhead Systems Committee.

TABLE I

PRIMARY DISTRIBUTION VOLTAGES IN USE BY COMPANIES REPORTING

			% of Companies
	2200 to 2400 volt only		21.0
Star	2200 to 2400/3810 to 4136 volt only		10.0
Star	4000 with 2200 to 2400 volt, 3-phase systems	9.5	
Star	4000 with 2200 to 2400, 2-phase systems	1.5	
Star	4000 with 2200 to 2400, 3-phase and 2-phase systems	4.2	
Star	4000 with 2200 to 2400, 3-phase and 1-phase systems	5.3	
		—	20.5
Star	4000 with 4400 to 7200 volt	3.3	
Star	4000 with 4400 to 13,200 volt	4.2	
Star	4000 with 11,000 to 13,200 volt	1.5	
		—	9.0
Star	4000 with lower and higher voltages		11.5
	2200 to 2400 volt with 4400 to 6900 volt		21.0
	2200 to 2400 volt with 4400 to 13,200 volt		2.7
	2200 to 2400 volt with 11,000 to 13,200 volt		4.3
			100.0

A study of Table I shows that 10 per cent of the companies are operating solely a 4000 volt Star System, and that 20 per cent are still operating in addition some 2200 to 2400 volt circuits. While the major part of their systems is 4000 volts Star, it is reasonable to assume that a total of 30 per cent will be operating solely 4000 volt Star Systems as soon as changeovers are completed.

In addition to these companies, 9 per cent are operating 4000 volt Star for concentrated load areas, and are using higher voltages for isolated towns and rural lines. To carry our conclusion still further, it may be safe to assume that 11 per cent of the systems operating 4000 volt Star Systems with some load still at 2200 to 2400 volts with higher voltages for rural services will, in the near future, eliminate the lower voltage circuits and operate at 4000 volt Star with a higher voltage for isolated loads. Therefore, at the present time the trend shows that a total of 51 per cent of the companies are using 4000 volt Star for a large portion of their distribution load. Of the remainder, approximately 24 per cent have indicated a tendency to go directly from 2200/2400 Delta Systems to a higher Delta voltage for their concentrated and rural load. This leaves 21 per cent who so far have taken no steps to increase their distribution voltages and 4 per cent who still operate a 2200/2400 volt Delta System with 11,000/13,200 volt Delta for concentrated load and rural service. As load densities increase so that higher voltages will be necessary, it is possible that a large number of these companies will change over their lower voltage Delta Systems to 4000 volt Star Systems.

A comparison of systems of all voltages and a tabulation showing the percentage of companies using each system was included in the serial report "Electrical Problems of Distribution" (Publication No. 267-15).

A company operating a 2300 volt system, whether single-phase, two-phase, or three-phase Delta, may change over to a 4000 volt Star System with the least expense and derive the benefit of greater capacity supplying larger areas from one substation with combined light and power load. Where rural service is considered, the practice indicates the use of a transmission voltage of 11,000 to 13,200 volts, or, if the distances are not too great, the adoption of one of the Delta Systems from 4600 to 7200 volts for this use (so that a higher voltage Star System may be used in the future). Therefore, it may be advisable to maintain two voltages and to have two stocks of transformers for supplying the distribution load on both systems.

For residential service, business districts of low load density, rural and small towns covering limited territory, 2300/4000 volts finds a definite application. A higher voltage Delta System for concentrated business sections, rural service and small towns in scattered territory, may be economical and desirable.

TYPES OF CONNECTIONS

Outline of Types

In general, all types of distribution circuits may be divided into three classes. Each class may have several subdivisions as given in Table II. Each company has coined a name for its particular type of circuit, so that it is very difficult to hold the subdivisions of these general classes to a minimum. In this report an effort has been made to include all the major differences of the various types of circuits without covering a multitude of those which have only certain peculiar features differentiating them from the general types. The outline in Table II classifies the various types.

TABLE II

TYPES OF PRIMARY AND SECONDARY DISTRIBUTION SYSTEM CONNECTIONS

1. *Primary System*
   a. Radial
      1. Main
      2. Feeder and Main
      3. Segregated Phase
      4. Duplicate Service
      5. Parent Feeder
   b. Loop
      1. General Distribution
      2. Bulk Load Distribution
   c. Network
2. *Secondary System*
   a. Radial
   b. Network
      1. Isolated.
      2. Interconnected.

It will be noted that in describing any particular type of distribution system it will be described first in respect to the type of primary system and, second, to the type of secondary system. This is essential to a clear understanding of the particular system, since the primary system may be one of several types entirely different from the type of secondary system. Thus, a radial secondary system may be supplied by a radial, loop or network type of primary. The same may be said of a secondary network. Therefore, the dual classification is recommended.

Primary Systems

(a) Radial

The radial type of distribution circuits, in some form, is in most common use today, and by means of diagrams some of the different types into which this general group of circuits has been divided will be described. The various classifications of the radial systems are simply modifications necessitated by local conditions.

(1) Main

The most common type, or radial main, as shown in Fig. 1, is used where a feeder is installed from a substation into a given area and takes care of all of the load in that district. The feeder itself will run as near to the center of load as is practicable, and a feeding point established which may be used as a basis of regulation. From this feeding point, radial mains are run in all directions with laterals to pick up the load. In general three-phase mains are run through the heavily loaded areas with single-phase taps to pick up isolated single-phase loads.

An adaptation of the radial main system is what is popularly termed the tree or herring-bone type of feeder. This is similar to the radial and main feeder except that the feeder portion supplies the system of mains at that portion of the feeder area nearest the substation instead of at the center of the load. Its application is principally in small towns and rural districts. Undoubtedly, it is the result of extending a single line along a road or isolated street to serve customers along that particular thoroughfare. As territory on both sides of the line develops, side taps and extensions along intersecting roads result in it being expanded into a feeder supplying a sizeable area. The schematic connections may be represented as shown in Fig. 1 if it is assumed that the feeder is connected at one end instead of the center of the feeder area. This type of feeder is adaptable only to areas of light load density, as the regulation and losses are greater.

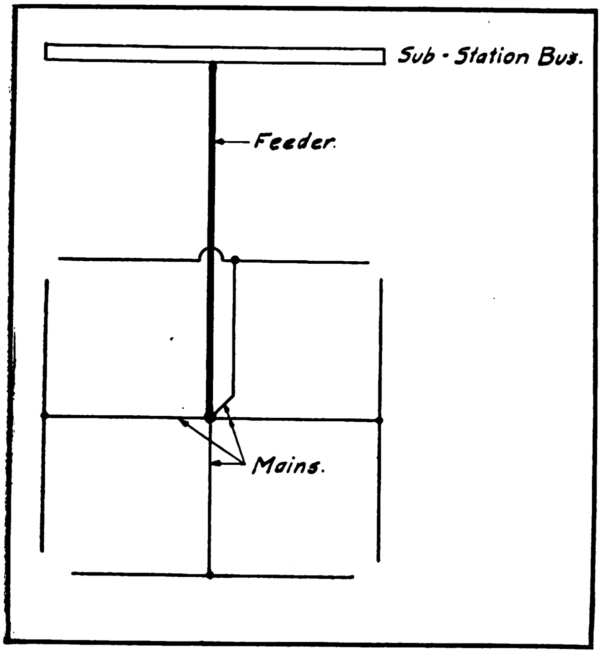

FIG. 1—RADIAL, MAIN PRIMARY FEEDER.

(2) Feeder and Main

The type known as the feeder and main, as shown in Fig. 2, consists of a heavy copper four-wire main, extending through a district or possibly between substation areas, and divided up into feeder lengths. Each feeder length is sectionalized and connected by a feeder to an adjacent substation. Laterals are installed from the main into adjacent load areas. This is merely a modification of standard radial system where geographical conditions require narrow feeder areas or where high load densities exist in a narrow area.

Mains Terminated On Same Pole As Tie Point.
Laterals On Each Section.
Sectionalized Main.
Feeder.
Station B Bus.

FIG. 2—FEEDER AND MAIN PRIMARY FEEDER.

(3) Segregated Phase

The segregated phase system, Fig. 3, is a slight modification of the radial main in which single phase mains are run in three directions from the feeding point, and each phase handles all the load in a definite phase area instead of carrying the three phases into each district.

(4) Duplicate Service

A duplicate service scheme as shown in Fig. 4 is really a direct application of the radial main to an important load area, such as a business district, where continuity of service is paramount. In this system the radial main circuits are interlaced so that all customers or distribution banks may be served by two separate circuits; preferably circuits from two different stations. The scheme is not in common use as a distribution circuit.

B Phase Area
C Phase Area.

FIG. 3—SEGREGATED PHASE PRIMARY FEEDER.

(b) Loop

The second general class of circuits known as the Loop System is very common for transmission service, but recently has been more frequently used in distribution systems. In general, all types of loop circuits are the same, although two different applications are in use.

First, as shown in Fig. 5, the large customers' feed consists of a feeder extending from one substation out through a territory and either back to the same substation or to one adjacent, with large customers connected in series and with protection equipment on both sides of each customer's service. In case of trouble on the feeders the switches nearest the fault will open, but no banks will be out of service.

Second, the distribution loop, as illustrated in Fig. 6, is very similar to the large customers' feed, but the feeder is equipped with automatic sectionalizing

switches to cut out a bad section in case of trouble, leaving the rest of the feeder in service. The feeder sections between such sectionalizing switches may have banks connected directly to them or laterals which reach out into adjacent territory and supply load. The loop is relayed with time delay relays or pilot wire protection so that the two switches nearest the trouble will open, leaving only that section out of service.

(c) Network

A primary network has been proposed and is being used in at least one city which will be capable of indefinite expansion as far as area and load are concerned. Fig. 7 illustrates this type of circuit. This system consists of a number of radial transmission circuits extending from a generating or substation bus to the load, with one stepdown bank connected directly to each circuit. The secondary of this stepdown bank, presumably at 4000 volts, would be connected to a bus through an automatic oil switch, from which lines would extend in four directions, each line tying into a similar bus some distance away. These tie lines from which laterals would be installed are protected by an automatic oil switch at each end. Distribution transformers with their respective radial secondaries would be connected to these ties and laterals and thus serve the area.

Secondary Systems

(a) **Radial**

The radial secondary system is so widespread in its use and so familiar to distribution engineers that it need neither be described nor discussed. It will suffice to say that a radial secondary system consists of a number of isolated secondaries, each supplied by one transformer or transformer bank.

(b) **Network**

The secondary network type of distribution has gained recognition very rapidly in the last few years, and while in most cases it is confined to underground installations, it will be discussed here as one of the types under consideration.

A radial primary, secondary network, as illustrated in Fig. 8, can be used quite extensively in overhead territories and has proved very successful. It consists of banking several sets of transformer banks common to the same primary and secondary with protection on both the primary and secondary sides. This insures service on the secondary, although one transformer on the network may have failed. Surplus capacity on the secondary must, of course, be installed to take care of the failure of one bank on each network. Periodic load check on each bank and inspection of the primary and secondary fuses must be made to make sure that all banks are in service.

The multiple primary feed network, Fig. 9, is most applicable in districts of high load density. In this case all transformers are tied solidly to a primary feeder of the radial type and in turn tied to a common secondary bus through automatic low voltage network protectors. This type of system has been covered in detail in other papers, and no attempt will be made to discuss it beyond its comparison with other types of distribution circuits.

The loop primary feed network system, as shown in Fig. 10, is a very recent combination of two important types of distribution circuits, and it therefore may be considered as a separate class of circuit. This system consists of several distribution loop circuits operating between two substations or from one substation bus with automatic sectionalizing switches between each transformer installation. Transformers are connected directly to these loop feeders and through secondary fuses supply a common secondary bus. This type of circuit eliminates the necessity of installing as great an amount of surplus transformer capacity as is needed in the multiple primary network, but requires a much greater surplus of feeder capacity. In case of a primary feeder failure, only one bank on that feeder is out of service due to the selectivity of the automatic sectionalizing switches.

APPLICATION OF VARIOUS TYPES OF SYSTEMS

In territories of medium low density the radial main system offers a very desirable type of circuit to give good regulation and permit the use of three-phase equipment over a large territory. Load may be balanced between phases on this type of circuit and thus utilize the full capacity of the feeder itself. The radial main system may not be economical in territories of very low load density covering a large area. Interconnection with adjacent feeders is usually maintained so that the portion of the feeder between the substation and feeder points may be cut out and service maintained by connecting the mains to adjacent feeders.

In changing from a single-phase, 2300 volt system to a 4000 volt Star system, the segregated phase type of circuits may be adopted with a minimum amount of copper. This type of circuit should be most economical for districts with low load density covering a considerable territory. Independent voltage regulation at the feeding point may be maintained on all phases. It is difficult to balance the phases on this type of circuit and it does not permit the use of three-phase equipment except when adjacent to the feeding point. An extensive rearrangement is necessary in order to take care of added load without excessive voltage drop or unbalancing of the phases. In order to take three-phase load, considerable revamping is necessary in adding additional copper. Neutral loss is increased but copper cost in mains is reduced.

The duplicate service scheme offers a very reliable service with a minimum outage to service such as business districts, hospitals and the like. It permits taking feeders out of service without serious interruption to the customer, and also permits regulating the load on each feeder. This type of circuit necessitates the installation of two oil switches or sets of fuses at each installation, and these require constant maintenance. An excessive amount of copper is required in order to cover a large area with this type of service, and it is only justified in concentrated business districts where continuity of service is an important factor. It is the opinion of many engineers that this scheme has no paramount advantages for supplying business areas if the successful operation of a multiple primary feed secondary network is possible.

The feeder and main system offers the best type of circuit for narrow districts of medium load density with laterals reaching out to adjacent lower density load areas. The phases may be readily balanced and extensions added with the least amount of new construction. During low load periods the feeder may be taken out of service and the main tied to the adjacent main section without excessive voltage drop. This permits maintenance of the feeder and all switches at the station without an interruption of service. This type of circuit has no advantage in large territories of very low load density due to the heavy copper main necessary between substation areas. This may be used where a narrow business area has developed requiring additional feeders due to increased load densities.

The loop system offers a very reliable source of supply to large customers, with the minimum amount of copper, but with the installation of two oil switches at each customer's installation. This system when used to supply general distribution may require the installation of automatic sectionalizing switches at frequent intervals so that only a small amount of load will be dropped in case of the failure of one section of the feeder. The general advantages and disadvantages of both types of loop circuits are similar. The loop is a very reliable source of energy for combination power and light loads at a uniform voltage. Division of the load may be controlled from either end of the loop, and one end of the circuit may be taken out of service without affecting the service of the loop. The loop system necessitates the installation of two oil switches at the substation to carry the load of one circuit and also the installation of sectionalizing switches, either automatic or non-automatic.

The radial network in territories where a few adjacent banks supply important loads will insure the load against an outage due to transformer failure but not due to primary feeder failure. This system permits paralleling several banks of transformers covering adjacent blocks on the same secondary, provided primary and secondary fuses are installed to supply and to protect the service against the failure of one transformer. In such cases the secondary fuses should not be placed for overload protection, but for failure of the transformer itself.

The multiple primary feed is especially adaptable to concentrated business areas where continuity of service is of major importance by the proper interlacing of primary feeders supplying the low voltage secondary. Any primary feeder may be out of service without materially affecting the loading of the remaining transformers or the voltage on the secondary. It also permits the combination of light and power on the same secondary. Suitable automatic low voltage network protectors are on the market which give very satisfactory operation. The expenditure necessary to set up such a network is not justified unless high load densities exist which will render a network economical. Additional transformer capacity must be installed to take care of the possibility of one feeder being out at any time without causing excessive voltage drops between remaining banks.

The loop primary feed network employs the combined features of the loop and the network as given above, and is more adaptable to territories of lesser load density where continuity of service is an important factor. Such an installation does not necessitate as great an amount of spare transformer capacity, since only a small section of a feeder may be out of service due to primary feeder failure.

The proposed primary network will permit a very reliable source of supply for moderately loaded areas

The scheme is very flexible and is so arranged that trouble on any section will affect only a small area. This type of circuit would be very effective in residential areas of medium load density where the type of service rendered by the secondary network is desirable but where the load does not warrant its adoption. Consideration must be given the type of oil switches to be used so that they do not prove to be a hazard. As the voltage drops are small, due to the close spacing of small substations, unregulated feeders may be used. They may also be used for districts having light load densities. As load density increases more small substations may be added. Substations are small and simple, consisting only of a transformer bank and five oil switches. This system may be used where it is ultimately intended to change over to a multiple primary feed secondary network.

ADAPTABILITY OF VARIOUS SYSTEMS TO FUTURE GROWTH

In order to take care of increased load beyond the feeder capacity, both the radial main and segregated phase type often require considerable rearrangement and construction. New feeder areas must be set up and load cut over from existing feeders to form a new feeder area. In the segregated phase scheme, especially, considerable difficulty may be experienced in relieving the load on existing feeders and still maintain a balanced phase condition. A new switch position at a substation must be provided and a feeder installed from this substation to the center of load of the new feeder area. With a radial main system new feeders may be created readily if a more or less continuous network of primary mains exists with junction boxes at each intersection point. The procedure in establishing a new feeder is to install the new feeder to the junction box at the new feeder joint and open the boxes at the boundary of the new feeder area. With an overhead system, the procedure is simpler by virtue of the fact that lines may more readily be worked on when alive.

Where the duplicate service scheme is used, new feeders must be installed to take care of a desired load when additional capacity is needed. In general, a rearrangement similar to the radial main scheme is required. Arrangement must be made, however, to extend an existing feeder into the territory for the emergency service.

The feeder and main type is the simplest of all the radial feeder systems to readapt for increased load. The main may be cut or redivided and a new feeder switch position in the substation connected to the new main section without any further expense or rearrangement.

The general distribution and large customer feed loop system may be loaded to the limit of that which can be carried from one end without excessive voltage drop, giving due consideration to existing loads. Beyond this point, if new load is added, a separate loop must be installed from two new feeder positions at the substation.

The radial network may be extended up to the limit of the feeder, at which time it must be sectionalized and new feeders added. In this type of system it would be preferable to have several small networks instead of grouping all transformers on one feeder onto a common secondary due to the limitation of present day fuses. Growth of load may be provided for in the same manner as for the radial main system.

The multiple primary feed network is very flexible and new feeders may be interlaced with the existing feeders to take care of increased loads. Each bank on the new feeder is tied to the existing secondary grid or an extension, if in new territory.

TYPICAL INSTALLATIONS

Operating circuit maps were requested from a number of companies having 4000 volt distribution systems and maps were received by the committee which illustrated in detail the important features of several of the typical circuits. These maps have been revised to be applicable to a typical area, and, as reproduced here, illustrate in a comparable manner applications of the various types of systems.

Radial Main

Fig. 11 shows a simple radial circuit supplying single-phase and three-phase load.

Segregated Phase

Fig. 12 shows an example of a segregated phase feeder. This circuit consists of a feeder and three-phase mains, tied into adjacent feeder areas for emergency connections. Single-phase laterals are run from the mains so that definite areas as marked are designated for each phase. In this type of circuit, three-phase laterals may be extended to pick up power loads, although all lighting is connected according to specified phase areas. Each phase is regulated for its own feeding point.

Duplicate Service

Fig. 13 illustrates an application of duplicate service to large customers. These circuits are interlaced throughout an outlying business district supplying duplicate service to important buildings. While these circuits are not solely duplicate service feeders, they illustrate the method of interlacing feeders for this type of service.

Feeder and Main

Fig. 14 shows the use of a feeder and main system. A sectionalized main extends through the two boroughs, each section being supplied by a feeder from one of the substations. The laterals and transformer connections for the entire area were left off so as not to make the map unreadable. A section of one lateral is shown to illustrate the transformer layout. This main eventually will be extended into adjacent substation areas forming a possible main bus tie between substations. The main sections and the feeders are connected by means of pole top disconnecting switches to its respective main sections.

Loop

Fig. 15 shows a typical loop layout between several substations. These circuits supply large customers' installations as well as large banks for low voltage distribution. Due to the short distance between installations pilot wire protection is used in most installations.

Radial Network

No maps illustrating an overhead system radial network were received, and while the circuit shown in Fig. 16 is not entirely adaptable to overhead use, it will illustrate the possible use of the radial network system. The solid lines represent a primary feeder with its tie points. Large transformers are connected by fuses between the primary and the secondary. The secondary, which is shown in dotted lines, also has emergency ties to adjacent secondaries. This map shows a more extensive secondary network than would be feasible in an overhead area due to the additional hazards of trees and storms. Radial networks vary in extent from the simple one having two transformers whose secondaries are tied, to a very complete interconnection.

Multiple Primary Network

Fig. 17 shows the primary layout of a multiple primary feed secondary network. The primaries consist of 4000 volt or higher voltage feeders interlaced to supply transformer installations, so that no adjacent banks are connected to the same feeders. Each bank of transformers is 300 kv-a. and they supply concentrated loads in buildings in which the banks are installed, and also smaller loads connected to street secondary mains. If one feeder fails it automatically disconnects itself from the network by means of the automatic network switches and the entire load is carried by the remaining feeders. This installation is entirely underground and is used only to illustrate this type of circuit.

PART II

METHODS OF CHANGING OVER TO 4000 VOLT SYSTEMS

SCOPE

The greatly increased consumption of electrical energy has rendered the 2200 volt distribution systems of many utilities inadequate to economically meet the ever-growing demand. The present tendency among many utility engineers appears to be toward distribution at 4000 volts, 3-phase, 4-wire Star, utilizing to a great extent the existing equipment of the 2200 volt system now in use. Where increased capacity and improved regulation are required at minimum cost, this change, if adequate, is obviously the most practical method.

A number of utilities have made the change with apparent satisfaction, and others are contemplating similar changes. This subcommittee has endeavored to learn from the companies that have changed the advantages and disadvantages that have developed and the methods used in changing their distribution systems. From answers received, it appears that the 4-wire, 3-phase Star systems have many advantages over the 3-wire, 2200 volt systems, the greatest of which is that transmission effected at 3800 or 4000 volts nearly doubles the range of distribution. An important point to be considered in systems having long single phase branches is that a 4000 volt, 4-wire system retains 2200 volts in these branches; whereas, a straight doubling of voltage overcomes this deficiency. In the 4000 volt, 4-wire system the neutral wire runs near earth potential and is usually grounded at the generating station or substation. It is necessary, therefore, that more attention be paid to the insulation from ground of phase wires and connected apparatus such as fuses, than in the 2200 volt system, since a ground on any phase wire causes a short circuit. Linemen also must exercise greater care when working on lines.

It is very difficult in a report of this character to go greatly into detail, due to the fact that details concerning a voltage changeover must, necessarily, vary considerably in every case. Each company will have its own individual problem which will, no doubt, differ appreciably from the problem facing any other company, considering a similar voltage change. Therefore, the details of voltage changeovers cannot be set forth at any great length without first making a number of hypothetical assumptions as to existing conditions. Such assumptions are not justifiable except to provide a mere example. Since such an example could hardly fit the actual requirements of any company, it could be of use only in pointing the way to general conclusions and methods applicable in every case. It would seem better to formulate and state at once such conclusions and general methods as have been gathered from the questionnaire replies received from various companies.

If the system is 3-phase, all parts of the circuit must be changed at the same time. This necessitates reconnection of transformers, regulators, switching apparatus, etc., at the substation. As there are usually two buses, one of these is set aside for the new connections and a neutral bus is added. The circuits are then changed from the old bus to the new one as the work progresses. When a new substation is built the work is greatly simplified in that the station can be arranged for the new system, new circuits are run out to where the old ones are to be picked up, and terminated in disconnecting switches or disconnecting potheads, as the case may be.

So far as conductor spacing is concerned, considerably higher than 2200 volts may be safely carried on lines at single pin spacing of 14 in. without violation of safety codes, although many companies have found it advisable to increase the horizontal spacing with the new voltage. If wider clearances than those in present use should be necessary or advisable, considerable rebuilding of the overhead lines may be involved. Distribution transformers need not be replaced in changing to a 4000 volt, 4-wire system from a 2300 volt Delta system. This effects a large saving.

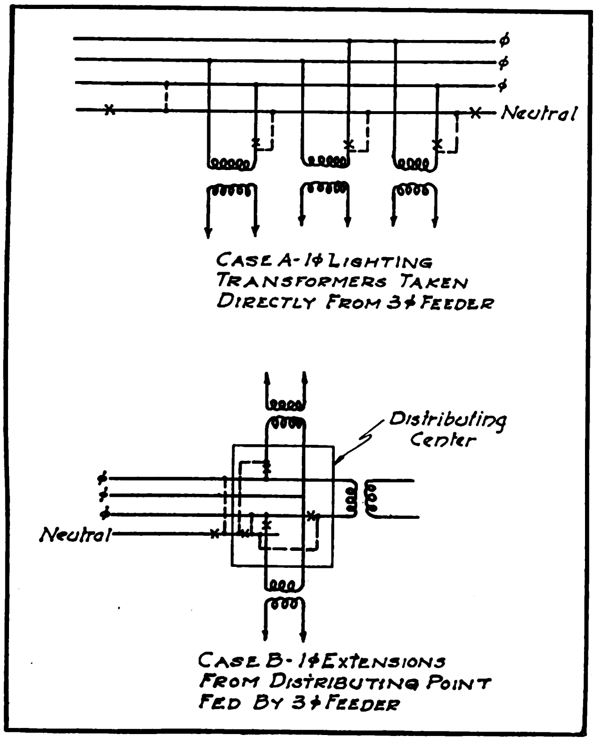
The determination of the exact amount of equipment to be replaced or the amount of rebuilding necessary or advisable can only be made after a thorough survey of any case in question. It will, however, depend to a large extent upon whether or not the higher voltage has been foreseen and apparatus purchased with the future change in mind. If a great deal of replacement is necessary, it may be better under certain circumstances to build a new system and change over to it. In many instances such a procedure would probably result in less outage than in the case where the old distribution system is changed over to a higher voltage. This would be particularly true where a considerable replacement of service equipment is necessary. In most cases, however, the existing equipment, or a large percentage of it, is suitable for operation at 4000 volts, and it is generally best to use it, and change the existing system to the higher voltage. The exact costs of changing are rather difficult to determine, and general figures can be of little value.

So far as the effect of the type of distribution system in use on the method of changeover is concerned, it does not seem that the general procedure as given below would be varied to a great extent in any case. Where the radial main type of distribution is used, interruptions to power customers could be considerably lessened, where necessary, due to the possibility of duplicate feed with a temporary bank of transformers or portable substation, while reconnecting the primary of the main bank. Even though temporary banks were not used, a smaller number of crews would be needed to make the changeover with the same length of service interruption. The latter fact would probably be true also with the loop system, dependent on the length between sectionalizing switches and the number of services on a section. The length of neutral required with a loop would be a maximum. Where the segregated phase system is used to a large extent, the installation of the neutral is simplified, since it need only run to the feeding center.

The methods of changeover applicable in most cases are given below:

CHANGING 2300 VOLT, 3-PHASE, 3-WIRE TO A 2300/4000 VOLT 4-WIRE SYSTEM

A complete field survey should be made prior to the change; a set of construction maps made showing all connections, all branches and transformer connections, and instructions made up, including detailed prints of all changes necessary. Each Division, that is, the Station, the Underground and the Overhead Departments' work should be outlined and coordinated into a set of instructions, including the work to be done and the time for doing it, and the gangs organized in such a manner that each department would have its part of the work completed without any conflict with the others. Temporary work and all permanent construction work that can be completed prior to the actual cutover should be done. Circuits are usually changed over on Sundays in order to inconvenience power customers as little as possible. On the Saturday preceding the change each power customer having polyphase current should be visited, the rotation of his motors marked and arrangements made for getting into his premises to make tests the following day.



ϕ
ϕ
ϕ
Neutral
Case B-1ϕ Extensions From Distributing Point Fed By 3ϕ Feeder

FIG. 18—METHOD OF TEMPORARILY CONNECTING NEUTRAL IN CHANGING OVER TO THREE-PHASE, FOUR-WIRE SYSTEM.

The outside work consists of installing a neutral wire parallel to the other three wires for connection to all the single-phase lighting transformers on the circuit. It is usual to have the neutral wire disconnected from the station and cut open in at least three places corresponding to the phase distribution of the completed circuit. Then connect portions of this neutral by jumpers to the existing circuit, and connect all the single-phase transformers to it until ready to make the change, when the jumpers are cut off and the neutral wire connected through and to the station bus, as is shown in Fig. 18. At the time the feeder is shut off, or shortly before, if possible, a crew is put to work opening cutouts on three-phase transformer banks. As soon as this is completed, service can be restored to the single-phase load with minimum interruption. In cases where transformer banks have been operated open delta, the necessary third transformer for the 4-wire arrangement, if used, should be installed previous to the new connection so that it is only necessary for the gangs of men to go over the circuit and change the connections for 4-wire operation as in Fig. 19.

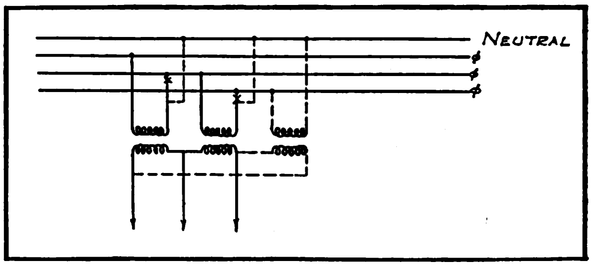

FIG. 19—METHOD OF CHANGING OVER 2300 VOLT OPEN DELTA BANK TO 4000 VOLT STAR DELTA.

The possibility of reversal of phase rotation is, of course, present in making these changes and a form of 2-phase or 3-phase motor, as the case may be, or a phase rotation indicator should be used for checking to see that the original direction of rotation is not reversed. Serious damage to machinery may be caused by failure to observe proper precautions in this respect, since few installations are equipped with reverse phase relays.

CHANGING 2300 VOLT, 2-PHASE, 4-WIRE TO 2300/4000 VOLT, 3-PHASE, 4-WIRE

In order to balance the load on the new system a survey of each circuit should be made; the transformers reassigned to the three phases; temporary cutouts installed, and connections run for the transformers which are to be connected to the new B and C phases, Fig. 20. Each circuit may be divided into sections and sectionalizing switches installed on the phase wires. Separate orders are made up for each section and a line crew assigned to that portion of the circuit if the above practice is followed. At the time scheduled for the changeover, crews proceed to the location of the disconnecting switches controlling the section for which they are responsible, and upon word from the man in charge the circuit is cut from the old to the new bus and phase A immediately energized. With this arrangement it is possible to care for the lighting customers whom an interruption would seriously inconvenience, by arranging for their supply from phase A. Each crew then proceeds to pull the disconnecting switches on phases B and C, and then the transformer fuses on these two phases. Where single phase lines branch off the circuit, disconnecting switches may be installed previously, so that it is but necessary to cut the old line taps at these switches. When all of the main disconnecting switches have been pulled, phases B and C are energized, and as each crew finishes clearing its section and reports back at its starting point, it tests phases B and C at the disconnecting switch. If found clear, the switches are then thrown in. As soon as these phases are made alive, fuses are installed in the new cutouts, thereby connecting the transformers to their proper phase.

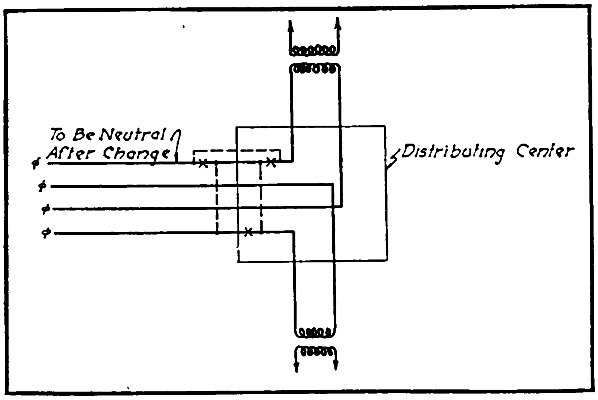

FIG. 20—TEMPORARY CONNECTIONS FOR FUTURE NEUTRAL ON TWO-PHASE, FOUR-WIRE CHANGE TO THREE-PHASE, FOUR-WIRE.

An interruption of from six to eighteen hours is generally required to change over large power customers. In some cases this long interruption would cause great inconvenience to the customer, and in these special cases a duplicate installation is usually made previous to the discontinuance of the 2-phase primary feed, and the job is handled as mentioned previously in connection with single phase.

One large utility reports that the majority of its power customers' motors were reconnected for 3-phase before the circuits were changed and these customers were supplied by using transformers having 86.6 per cent taps on the secondary and giving them a Scott Connection during the time between changes.

SPECIAL TRANSFORMERS AND CONNECTIONS

In changing over from 2-phase to 3-phase Star distribution there are many 3-phase loads to be supplied from 2-phase primaries and 2-phase loads to be supplied from 3-phase primaries. These transformations cannot be made with the standard transformers. Two special designs of transformers are available for this purpose. One of these is shown in Fig. 21 and is referred to as Type B Special. This transformer has a double primary winding with three taps, the voltages of which are indicated in Fig. 21. The secondary consists of a single winding with a tap at the mid-point. The other design, referred to as the Type A Special, is also shown in Fig. 21. It is similar to the Type B Special, but differs in having a Scott (87 per cent) tap in the secondary winding and only one tap (87 per cent) on the primary. The rating is based on the Scott voltage (4156 volts), instead of the full voltage (4800 volts), so that, by using the full voltage, 13 per cent more than its rating may be delivered without overloading the transformer.

Both of these special transformers were designed to transform from 2400/4156 primary voltage to 120/240 volt secondary. They can be used also on 2200/3810 volt or 2300/4000 volt primary systems. Fig. 21 shows the voltages of the leads of both transformers and some special connections using the Type A Special.

GENERAL COMMENTS

When contemplating the changing of a system to 4000 volts, 4-wire, a great deal depends upon the amount of careful study and preparation which has been made of the subject prior to the changeover. To facilitate the general progress of the work and to avoid interruptions, it is a good plan to supply each line crew with a set of construction standards in blueprint or book form of a convenient size, in order that they may familiarize themselves with the various types of construction to be used. The National Electric Light Association Suggested Specification will be found useful as a guide for this, but detailed plans, specifications and bills of material should be provided for the kind of construction to be followed under actual conditions and suited to the particular kind of system under construction.

It is strongly urged that utilities considering this change take into account that any false economy, neglecting to properly prepare their lines for the change, will cost them dearly in customers dissatisfied by impaired service, since service can be maintained only when the lines are in good condition. The possibility of tree grounds must be eliminated either by trimming, using higher poles or tree wire; any defective insulators, lightning arresters or junction boxes must be replaced, slack must be pulled from conductors, and in some instances conductor spacing must be increased. It is well to pay particular attention to arranging conductors in fixed relative positions throughout the system. Interruption of customers' services should be worked out with care since good will is always an important item. The actual handling of details will depend to a large extent upon the location, size of the company and type of service to be interrupted, together with the length of interruption necessary. In some sections advertisement in newspapers of proposed changeovers and the time work will be started and completed may be all that is necessary. In some cases private interviews may be the only solution to obtaining an interruption; and in others, usually

large customers where the necessary interruption would cause great inconvenience, no interruption can be allowed and duplicate temporary service must be run in and connected before cutting over. A small company may use the first two methods; but a large company will generally use all with the possible exception of the newspapers, and in these cases interruptions are usually scheduled by telephone or personal interview. Still another method is to send printed notices by a messenger to the customer affected. This last method has been used to advantage by a number of companies.

SUGGESTED SPECIFICATIONS FOR OVERHEAD LINE MATERIALS, AND METHODS OF CONSTRUCTION FOR LOW AND MEDIUM VOLTAGE LINES

The Subcommittee on Overhead Line Materials and Methods of Construction for Low and Medium Voltage Lines was appointed:

1. *To ascertain the extent of the use of the suggested specifications for overhead construction materials prepared by a subcommittee and published by the Overhead Systems Committee in the Report in 1924, Publication No. 24-15. The material in that publication has been revised and appears in the Overhead Systems Reference Book, published by the National Electric Light Association in 1927.*
2. *To prepare, along the lines followed by the previous subcommittee, such new suggested specifications as were proposed by the member companies and manufacturers, which were thought to be warranted for publication.*
3. *To present construction drawings, showing the use of materials covered by the new proposed specifications, and photographs of transformer pole and cable pole installations, illustrating typical practice in various parts of this country.*
4. *To gather such information, in connection with the use of materials, as may be of interest to the member companies.*

PART I

USE OF SPECIFICATIONS SUGGESTED IN 1924

For this purpose the subcommittee mailed to 60 member companies a questionnaire asking whether each individual specification, published in 1924, was used by that company.

Number of questionnaires sent out....... 60
Number of questionnaires answered...... 45
Percentage of questionnaires answered... 75%
Total number of replies possible, 58 items by 45 replies, or...................... 2,610
Total number of replies received......... 2,581
Percentage of replies received........... 99%
Number of replies, affirmative....1400 or 54%
Number of replies, negative......1181 or 46%
95% of the specifications are used by over 20% of companies.
74% of the specifications are used by over 40% of companies.
50% of the specifications are used by over 60% of companies.
17% of the specifications are used by over 80% of companies.

The diagram, Fig. 1, explains graphically, the extent of the use of these N. E. L. A. suggested specifications.

The specification "D" numbers, plotted as abscissæ, are enumerated in the index to specifications immediately following. From letters received by the subcommittee from member companies, and the comments made by manufacturers, the N. E. L. A. specifications are receiving greater attention each year, and it is hoped that, where differences are minor, they will be adhered to in place of using special materials. It is to the common advantage, economically, of both users and manufacturers, to use those materials which are favored by a great number of companies.

PART II

PROPOSED NEW SUGGESTED SPECIFICATIONS

Certain of these suggested specifications have been added as revisions to those previously published.

1⅜-in. Pin and Insulator Threads

Following the report of original investigation made by L. J. Corbett of the Pacific Coast Section, N. E. L. A., the Committee has endeavored to make a uniform recommendation for the standardization of 1⅜ in. insulator threads and 1⅜ in. wood, steel, lead, and wire pin threads, bearing in mind that these threads should be correlated with the present standards for 1 in. pin and insulator thread. As the number of threads per inch are exactly the same for 1 in. and 1⅜ in. insulators, there appears to be no reason why they should not be identical. Due, however, to manufacturing processes, certain modifications had to be made in the metal pin threads.

Indexing of Suggested Specifications

The letter "D," representing the first unit of the index number, applies to material used in overhead line construction. The second unit in the index is a number, up to 1000, which signifies the specific type of overhead material referred to, the designating numbers being as follows:

Nos. 1 to 49 are assigned to poles.

Nos. 50 to 99 are assigned to preservatives and preservative treatment.

Nos. 100 to 149 are assigned to wood cross arms.

Nos. 150 to 199 are assigned to wood pins.

Nos. 200 to 399 are assigned to steel braces, bolts and similar equipment.

Nos. 400 to 499 are assigned to malleable and gray castings.

Nos. 500 to 599 are assigned to insulators.

Nos. 600 to 699 are assigned to wire and covering for wire.

Nos. 700 to 799 are assigned to transformers.

Nos. 800 to 899 are assigned to lightning arresters, cutouts, switches and similar equipment.

Nos. 900 to 999 are assigned to miscellaneous equipment not covered by the previous subdivisions.

The third unit of the designating number consists of two digits, representing the year in which the specification is proposed, and in case of revision the only change in the designating symbol will be the change in this unit of the index.

The fourth unit of the index consists of the letter "T," which shall be retained as long as the suggested specification is on trial, but will be dropped from the index symbol as soon as its use has become general.

Variations

The dimensions shown in the following suggested specifications are qualified by an allowable variation designated upon the drawings by small letters. These variations are deemed sufficient to allow for necessary deviation incident to present manufacturing practice or to slight differences in design. The amount of variation allowed is, as far as possible, consistent with the allowable accuracy of manufacture. Smaller variations are provided for thickness of plates or cross section of bars and rods that can be adhered to for the rougher operations of manufacture such as lengths cut by shears or locations of holes made by punches.

It is not intended that the manufacturer may avail himself of the allowable variation to reduce the amount of material furnished.

It is not proposed that the variations shall be accumulative either plus or minus, but shall refer only to the dimensions to which they are appended. Every dimension stated in the suggested specifications includes the allowable variation, as it is manifestly unfair to either the manufacturer or the consumer to be compelled to depend upon the individual judgment of the inspectors upon even relatively unimportant dimensions.

The small letters "a" to "k" in the accompanying key designate the amount of variation, and where the letter "x" appears, no variation is allowed. Where two letters are shown, the first letter designates the amount of variation *over* the dimension and the second letter designates the amount of variation *under* the dimension shown.

EXAMPLE

2¼"c —denotes an allowable variation of 1/16 in. over or under 2¼ in.

2¼"gc—denotes an allowable variation of ⅜ in. over 2¼ in., and 1/16 in. under 2¼ in.

2¼"dx—denotes an allowable variation of ⅛ in. over 2¼ in., but no variation under 2¼ in.

KEY TO ALLOWABLE VARIATIONS

Symbol	*Over*	*Under*
x	None	None
a	1/64 in.	1/64 in.
b	1/32 in.	1/32 in.
c	1/16 in.	1/16 in.
d	⅛ in.	⅛ in.
e	3/16 in.	3/16 in.
f	¼ in.	¼ in.
g	⅜ in.	⅜ in.
h	½ in.	½ in.
j	¾ in.	¾ in.
k	1 in.	1 in.

Review of Materials

D 70 and D 75—POLE PAINT. These suggested specifications are published for the guidance of those who still use paint, though numerous companies prefer the use of stain, which permits the evaporation of moisture and has some preservative qualities.

D 109—2-PIN CROSS ARM. This cross arm is extensively used for rural lines, when only two wires are to be installed. For assembly, see Fig. 57.

D 125—2-PIN CROSS ARM. Where a triangular arrangement of wires is desired this arm, together with pole top pipe pin D 355 or ridge pin support D 362, can be used. For assembly, see Fig. 58.

D 220—FLAT CROSS ARM BRACE. Dimensions of the 20 in. brace to be used with arm D 109, have been added on this drawing, first published in 1922.

D 225—ALLEY ARM BRACE. Dimensions of the 7 ft. brace have been added on this drawing, first printed in 1922.

D 230—ANGLE CROSS ARM BRACE. A 37 in. brace was added, to go with the arm D 125. Also, the dimension B for the 48 in. brace was changed to 18 in.

D 264—¼ IN. LAG SCREW. These lag screws are extensively used with service brackets.

D 264.1—⅜ IN. LAG SCREW. These lag screws may be used for mounting secondary racks.

D 270—ROUND WASHER. Two additional sizes for ⅝ in. and ¾ in. machine bolts were inserted on this drawing, first published in 1922.

D 282—GUY WIRE PROTECTOR. Two well-known types are shown. For assembly see Fig. 59.

D 299—MOLDING GUY PLATE. This plate is to be used with 1 in. molding, D 190-24. For assembly see Fig. 60.

D 322—PRESSED STEEL SPLIT CLEVIS and D 324—DROP FORGED ONE PIECE CLEVIS. Both types of clevises are for use with guy strain insulators. For assembly, see Fig. 62.

D 330—¼ IN. EXPANSION BOLT. This size is used for mounting service brackets, D 910.

D 332—½ IN. EXPANSION BOLT. This size can be used for installation of secondary racks, D 920, also for mounting eyelets and insulator clevises on walls.

D 340—1 IN. STEEL PIN. Three types of 1 in. steel pin, for use on low voltage lines, are shown. The threads for these pins should be checked with the gage, D 997.

D 350—STEEL PIN. For the present only drop forged type is shown, though there are other pins, such as hollow malleable iron type, well suited for the same purpose. An endeavor is made to limit the height to 14 in. by 2 in. steps.

D 355—POLE TOP PIPE PIN and D 362—RIDGE PIN SUPPORT. Pole top pipe pin is preferred by many to the ridge pin support. For assembly, see Fig. 58.

D 430—8 IN. ANCHOR PLATE and D 431—12 IN. ANCHOR PLATE. Cone anchors are still very popular, being efficient and low in cost. For assembly, see Fig. 61.

D 570—MULTIFIN GUY STRAIN INSULATOR. This drawing completes the series of guy strain insulators D 560-23. The large size is very adaptable for dead ending of large conductors.

D 650—GALVANIZED STEEL STRAND and D 660—COPPER COVERED STEEL STRAND. The tables of breaking strength agree with the values given in the Overhead Systems Reference Book.

D 900—WIREHOLDER. This wireholder has a large hole suitable for use of duplex service wires.

D 910—SERVICE BRACKET. Service brackets as shown are made by a number of manufacturers and differ only in minor details. For assembly, see Fig. 63.

D 920—SECONDARY RACK. This is the first attempt to standardize on the outline of the rack and the distance between mounting holes to permit replacement.

D 950—SPLICING SLEEVE. This sleeve is recommended by Pacific Coast companies and is preferred to a sleeve having a "figure eight" cross section.

D 970—SOLDER. For the convenience of member companies, the composition of wiping solder was added in the table. This composition has been found by several companies to be better than other combinations.

D 990—1 IN. and 1⅜ IN. THREAD IN INSULATOR. This drawing represents a proposed thread in insulator. This thread has well-rounded corners, this being necessary because of the character of the materials used in making porcelain. The principle of having the groove larger than the ridge is used because it is believed that this condition is necessary on account of defects resulting from uneven pitch, glaze unevenly filling up the corners and presence of chips and dust in the groove. The bottom of the pinhole is made with a liberal radius providing the necessary clearance to the top of the pin. This condition is necessary to take care of some pins found on the market. Attention is called to the fact that no allowable variations have been provided on this drawing, the thread fit to be checked with insulator gage D 995.

D 991—1 IN. and 1⅜ IN. WOOD PIN THREAD. This drawing shows a standard wood pin thread, such as is used by most companies, and is believed to be satisfactory. The permissible variation from the nominal size of diameter of the first thread is shown on this and the following drawings as being 1/64 in. "over" and nothing "under." It is believed that this condition will fit a greater number of insulators which are made somewhat oversize, and, though the pin may not enter as far as the top thread of the pinhole, it will insure a better fit than in the opposite case, when the pin is too small and the pinhole is too large.

On this drawing, as well as on the following drawings, another principle has been carried out: the pitch diameter of the pin rides on the root diameter of the porcelain. It is believed that in this manner the stress is developed at the base of the porcelain thread where it has maximum width.

D 992—1 IN. and 1⅜ IN. CAST LEAD PIN THREAD. This drawing shows the cast lead pin thread. Sufficient clearance is provided between the lead thread and the porcelain thread.

D 993—1 IN. and 1⅜ IN. WIRE PIN THREAD. This drawing shows the wire pin thread, such as is manufactured by a well-known hardware concern. The 5/64 in. radius for the wire thread was deemed necessary by the manufacturer to insure sufficient strength of this type of thread. This dimension is believed to be permissible in view of the adjustability of this type of thread.

D 994—1 IN. and 1⅜ IN. PRESSED STEEL PIN THREAD. This drawing shows the pressed steel pin thread, as made by another well-known manufacturer. This type of thread also has some adjustable features, and it has been found satisfactory by many users of this pin.

D 995—1 IN. and 1⅜ IN. INSULATOR GAGE THREAD. This drawing shows a proposed thread for an insulator gage. This thread resembles the thread of the wood pin, D 991, with the exception that the ridge is made 1/16 of an inch wide instead of 3/32 of an inch, because the gage, being made of steel, has no adjustable features. It is believed, however, that this thread will be a sufficiently rigid requirement for checking the insulator thread. The sliding rod, as shown on this drawing, must clear the top of the gage from ¼ in. to ⅝ in. This clearance should be definitely decided upon when a sample gage is made and tested on a sufficient number of good insulators.

D 996—1 IN. and 1⅜ IN. INSULATOR GAGES. This drawing shows two insulator gages. The 1 in. gage is made to resemble a wood pin because it was recently found that a wood pin would not enter an insulator, due to a shoulder in the insulator pinhole. This shoulder was provided by the manufacturer to increase the thickness of the wall at that point.

The 1⅜ in. gage is not provided with that feature because practically no wood pins are used for 1⅜ in. insulators. The general dimensions of these two gages were taken from actual gages used by one large company manufacturing porcelain insulators.

D 997—1 IN. and 1⅜ IN. INSULATOR PIN GAGES. This drawing represents pin gages. The design was illustrated in the report made by the Pacific Coast Electrical Association. Limitation shall be specified when sample gages are made and have been tried out on a sufficient number of pins.

D 70-28 T
(Tentative)

PRIMER POLE PAINT*

Scope

The paint required under this suggested specification shall be known as Primer Pole Paint, and shall be used as the primer paint. It shall be an easy flowing, good spreading, durable, ready mixed paint, having a finish of sufficient bonding power to be used with Pole Paint as the finishing paint.

General

Previous to the issuance of an order to any manufacturer, such manufacturer shall be required to submit duplicate samples to the purchaser, of not less than one quart each, of the paint representative of the material to be delivered under this suggested specification. All subsequent shipments shall be rejected if found inferior in any respect to the samples submitted, or not in accordance with this suggested specification.

Chemical Properties

The base pigments must be finely ground in properly refined, raw linseed oil, and reduced to a ready-for-use consistency with pure, raw linseed oil, approved dryer and volatile thinner.

Pigment

Pure pigments, free from grit, adulterants and all impurities, of the class necessary to produce the standard shades adopted, must be used. The combination shall include no barytes, nor other make-weight or inert material of low covering power, nor any substance soluble in water, nor aniline colors, lakes, or other organic coloring matter. It shall be finely ground, and not less than 99 per cent shall pass a 100-mesh sieve, and all shall pass an 80-mesh sieve.

Oil

The oil used must be strictly pure, well-settled and perfectly clear raw linseed oil, free from rosin, rosin oil, fish oil, mineral oil or other adulterants.

Dryer

The dryer used must be a good quality of lead or manganese dryer in the proper proportion to dry the paint within the time specified. Lead and manganese resinate dryers will be permitted.

The amount of colophony used, however, shall not exceed 1 per cent by weight of the paint.

Thinner

The thinner shall be turpentine volatile mineral spirits or a mixture thereof. The mineral spirits shall be a high grade naphtha conforming to the U. S. Federal Specifications Board, Standard Specification No. 16 for volatile mineral spirits for thinning paint. (Circular No. 98, Bureau of Standards; Technical Paper No. 323, Bureau of Mines.)

Water

Any water in excess of 2 per cent by weight shall be considered a cheapener and adulterant, and shall be sufficient cause for rejection of the entire lot without further test.

Pigment

Not less than 26 per cent nor more than 30 per cent.

Volatile Thinner

Not less than 18 per cent nor more than 22 per cent.

Raw Linseed Oil and Dryer Solids

Not less than 50 per cent.

Drying

The paint must dry, free from tack, within 12 hours and in not less than six hours under normal drying conditions.

Color

The color shall be the same in tone and shade as the standard samples or color cards submitted by the purchaser.

Packing

Unless otherwise stated on the purchase order, the paint shall be delivered in five gallon cans, bearing labels or stencils, giving the manufacturer's name and address, the kind and quantity of the contents, and the purchaser's order number.

Net weight or full measure only will be paid for. All cans shall have suitable openings (securely sealed during shipment) for the ready removal of the paint from the cans.

Inspection

Inspection and acceptance may be made either at the point of manufacture or upon delivery of the finished product. The manufacturer shall give the purchaser or his representatives such access to his works during working hours as is reasonable and necessary to determine the suitability of the material to be supplied and shall furnish all necessary apparatus, labor and other facilities for making the inspection herein called for without cost to the purchaser. The manufacturer shall eliminate all paint that he considers defective, according to this suggested specification, before offering any lot for inspection, or before shipping. Neither inspection, waiving of inspection, nor the purchaser's acceptance shall relieve the manufacturer from obligation to furnish paint in accordance with this suggested specification.

Paint not conforming with this suggested specification shall be rejected and the manufacturer shall replace such rejected paint with paint complying with this suggested specification at his own expense, or shall allow credit for such rejected paint.

---

*Several companies are satisfied with the use of Finishing Pole Paint D 75-28 T and omit the Primer Pole Paint D 70-28 T.

D 75-28 T
(Tentative)

POLE PAINT*

Scope

The paint required under this suggested specification shall be known as Pole Paint, and shall be used as the finishing paint. It shall be an easy flowing, good spreading, durable, ready mixed paint, having a sufficient hiding power to give a uniform finish with one coat of Primer Paint and one coat of Pole Paint on soft wood.

Preference will be given to paints displaying the greatest spreading rate with satisfactory hiding power.

General

Previous to the issuance of an initial order to any manufacturer, such manufacturer shall be required to submit to the purchaser duplicate samples, of not less than one quart each, of the paint representative of the material to be delivered under this suggested specification. All subsequent shipments will be rejected if found to be inferior in any respect to the samples submitted, or not in accordance with this suggested specification.

Chemical Properties

The base pigments must be finely ground in properly refined, pure, raw linseed oil and reduced to a ready-for-use consistency with pure, raw linseed oil, approved dryer and volatile thinner.

Pigment

Pure pigments free from grit, adulterants and all impurities, of the class necessary to produce the standard shades adopted, must be used. The combination shall contain no barytes, nor other make-weight or inert material of low covering power, nor any substance soluble in water, nor aniline colors, lakes or other organic coloring matter. It shall be finely ground and not less than 99 per cent shall pass a 100-mesh sieve, and all shall pass an 80-mesh sieve.

Oil

The oil used must be strictly pure, well-settled and perfectly clear raw linseed oil, free from rosin, rosin oil, fish oil, mineral oil or other adulterants.

Dryer

The dryer used must be a good quality of lead or manganese dryer in the proper proportion to dry the paint within the time specified. Lead and manganese resinate dryers will be permitted.

The amount of colophony used, however, shall not exceed 1 per cent by weight of the paint.

Thinner

The thinner shall be turpentine, volatile mineral spirits or a mixture thereof. The mineral spirits shall be a high grade naphtha conforming to the U. S. Federal Specifications Board, Standard Specification No. 16 for volatile mineral spirits for thinning paint. (Circular No. 98, Bureau of Standards; Technical Paper No. 323, Bureau of Mines.)

Water

Any water in excess of 2 per cent by weight shall be considered a cheapener and adulterant, and shall be sufficient cause for rejection of the entire lot without further test.

Drying

Pole Paint must dry, free from tack, when applied over the Primer Paint, within 24 hours, and shall produce a firm, flexible, insoluble, opaque film which shall show a high degree of resistance to change in color on exposure to weather, and shall conform to the following limits, by weight, in composition.

The Pole Paint comes in two consistencies: the one for summer use should be labeled Summer Pole Paint and the one for winter application Winter Pole Paint.

Summer Pole Paint†

Pigment

Not less than 40 per cent, nor more than 45 per cent.

Volatile Thinner

Not less than 5 per cent, nor more than 10 per cent.

Linseed Oil and Dryer Solids

Not less than 48 per cent.

Winter Pole Paint†

Pigment

Not less than 48 per cent, nor more than 53 per cent.

Volatile Thinner

Not less than 10 per cent, nor more than 15 per cent.

Linseed Oil and Dryer Solids

Not less than 35 per cent.

Color

The color shall be the same in tone and shade as the standard samples or color cards submitted by the purchaser.

Packing

Unless otherwise stated on the purchase order, the paint shall be delivered in five-gallon cans, bearing labels or stencils, giving the manufacturer's name and address, the kind and quantity of the contents, and the purchaser's order number.

---

*See footnote for D 70-28 T.

†For certain regions one kind of Pole Paint may be found sufficient.

Net weight or full measure only will be paid for. All cans shall have a suitable opening (securely sealed during shipment) for the ready removal of the paint from the cans.

Inspection

Inspection and acceptance may be made either at the point of manufacture or upon delivery of the finished product. The manufacturer shall give the purchaser or his representative such access to his works during working hours as is reasonable and necessary to determine the suitability of the material to be supplied, and shall furnish all necessary apparatus, labor and other facilities for making the inspection herein called for without cost to the purchaser. The manufacturer shall eliminate all paint that he considers defective, according to this suggested specification, before offering any lot for inspection or before shipping. Neither inspection, waiving of inspection nor the purchaser's acceptance shall relieve the manufacturer from obligation to furnish paint in accordance with this suggested specification.

Paint not conforming with this suggested specification shall be rejected and the manufacturer shall replace such rejected paint with paint complying with this specification at his own expense, or shall allow credit for such rejected paint.

D 90-28 T
(Tentative)

POLE STAIN

Scope

This suggested specification covers the quality of coal tar distillate (or coal tar creosote) to be used for the preservative treatment of wood.

General

Previous to the issuance of an initial order to any manufacturer, such manufacturer shall be required to submit to the purchaser, duplicate samples of not less than one quart each, of the stain representative of the material to be delivered under this suggested specification. All subsequent shipments will be rejected if found to be inferior in any respect, to the samples submitted, or not in accordance with this suggested specification.

Chemical Properties

The coal tar distillate or coal tar creosote called for under this suggested specification is obtained by the distillation of coal at a temperature high enough to yield a tar consisting mainly of compounds of the aromatic series. It shall be without adulteration.

1. The specific gravity at 38 deg. cent. compared with water at 15.5 deg. cent. shall be not less than 1.03.

2. The oil shall be completely liquid at 32 deg. cent.

3. The matter insoluble in benzol shall be not more than 0.5 per cent.

4. The water content shall be not more than 3 per cent.

5. The distillate based on water-free oil up to 210 deg. cent. shall be not more than 5 per cent; up to 235 deg. shall be not more than 25 per cent; up to 355 deg. cent. shall be not less than 60 per cent.

6. The residue above 355 deg. cent. shall have a float test of not more than 50 seconds at 70 deg. cent. if the amount exceeds 5 per cent.

7. The coke residue shall be not more than 2 per cent.

Color

The color shall be the same in tone and shade as the standard samples or color cards submitted by the purchaser.

Packing

Unless otherwise stated on the purchase order, the stain shall be delivered in five-gallon cans, bearing labels or stencils, giving the manufacturer's name and address, the kind and quantity of the contents, and the purchaser's order number.

Net weight or full measure only will be paid for. All cans shall have a suitable opening, securely sealed during shipment, for the ready removal of the stain from the cans.

Inspection

Inspection and acceptance may be made either at the point of manufacture or upon delivery of the finished product. The manufacturer shall give the purchaser or his representative such access to his works during working hours as is reasonable and necessary to determine the suitability of the material to be supplied, and shall furnish all necessary apparatus, labor and other facilities for making the inspection herein called for without cost to the purchaser. The manufacturer shall eliminate all stain that he considers defective, according to this suggested specification, before offering any lot for inspection or before shipping. Neither inspection, waiving of inspection nor the purchaser's acceptance shall relieve the manufacturer from obligation to furnish stain in accordance with this suggested specification.

Stain not conforming with this suggested specification shall be rejected and the manufacturer shall replace such rejected stain with stain complying with this suggested specification at his own expense, or shall allow credit for such rejected stain.

D 650-28 T
(Tentative)

GALVANIZED STEEL STRAND

Scope

This suggested specification covers galvanized concentric lay steel strand, made of round steel wires laid helically around a center wire. The center wire shall have the same quality and characteristics as the outer wires.

General

When ordering galvanized steel strand under this suggested specification the size and the strength rating of strand must be specified.

Variations

Each wire shall be accurate and uniform in diameter and of circular cross-section. The diameter of the wires 0.1 inch or larger shall not vary more than 1 per cent over or under. The diameter of wires less than 0.1 inch shall not vary more than one mil over or under the specified diameter.

Finish

Each wire shall be free from scale, splints, flaws, inequalities, and all other imperfections. The wires shall fit snugly around the center wire.

Material

The strand shall be made of steel of such quality as to comply with the strength requirements given in the following table:

Nominal Diameter	Number of Wires	Size of Individual Wires	Approx. Wt. Per 1000 Ft.	BREAKING STRENGTH, Min.			
				Standard	Siemens-Martin	High Strength	Extra-High Strength
¼ in.	7	14 BWG	121 lb.	1,900 lb.	3,060 lb.	5,100 lb.	7,600 lb.
⁵⁄₁₆	7	12	205	3,200	4,860	8,100	12,100
⅜	7	11	296	4,250	6,800	11,500	17,250
⁷⁄₁₆	7	9	399	5,200	9,000	15,000	22,500
½	7	8	517	7,400	11,000	18,000	27,000

(The breaking strength of the strand is taken as 90% of the sum of the breaking strengths of individual wires.)

Test of Breaking Strength

Samples shall be selected at random from finished strand and should be at least five feet in length, properly socketed and tested in a tensile testing machine. If the breaking strength of any test sample is found to be below the stated minimum value, tests shall be made upon two additional samples from the same coil or reel, and the average of the three tests shall be taken as the test value. Tests, wherein the strength is below specified minimum values, but which are, obviously, due to improperly applied sockets, shall not be considered.

When desired, tensile tests may be made on strand using gripping jaws of the testing machine in place of socketed specimens. If the strength values obtained meet the requirements of the table, tests on socketed specimens will not be required.

As an alternative to the above test of strand, breaking strength test may be made on each of the seven individual wires. Each wire shall have a strength of at least 15.9 per cent of the rated breaking strength of the 7-wire strand.

Joints

Joints may be made in wire when finished and ready for stranding. All joints shall be so made as to develop the ultimate strength of the wire. No joints shall appear in a completed strand closer than 150 feet.

Pitch and Lay

The pitch of the strand shall not be less than 12 nor more than 16 diameters of the completed strand, and the lay may be either right or left, as specified by the purchaser.

Galvanizing

Each wire shall be galvanized before stranding, and shall comply with suggested specification for hot galvanizing D 210-22.

Bending Test

Each wire of which the strand is composed shall withstand, without fracture of the steel, or the galvanizing on the outside of the bend, five consecutive wraps about a mandrel as follows:

Size of Wire	Size of Mandrel
14 BWG	¼ in.
12	⁵⁄₁₆
11	⅜
9	⁷⁄₁₆
8	½

In case the wire should fail on the first trial, two additional tests shall be made, and if no further failure occurs on either of these tests the wire shall be considered acceptable.

Packing

The strand shall be furnished in coils or on reels in lengths as specified by the purchaser.

Marking

Each coil or reel shall be tagged or marked inside and outside with the purchaser's name, address, the purchaser's order number, the size, kind and net weight of the wire, and the manufacturer's name.

Inspection

Inspection and acceptance may be made either at the point of manufacture or upon delivery of the finished product. The manufacturer shall give to the purchaser, or his representative, such access to his works during working hours as is reasonable and necessary to determine the suitability of the material to be supplied, and shall furnish all necessary apparatus, labor and other facilities for making the tests herein called for without cost to the purchaser. The manufacturer shall eliminate all strand that he considers defective according to this suggested specification, before offering any lot for inspection or before shipment. Neither inspection, waiving of inspection nor the purchaser's acceptance shall release the manufacturer from obligation to furnish the material in accordance with this suggested specification.

Strand not conforming with this suggested specification shall be rejected and the manufacturer shall replace such rejected strand with strand complying with this suggested specification at his own expense, or shall allow credit for such rejected strand.

D 660-28 T
(Tentative)

COPPER-COVERED STEEL STRAND

Scope

This suggested specification covers concentric lay, copper-covered steel strand made of round copper-covered steel wires laid helically around a center wire. The center wire shall have the same quality and characteristics as the outer wires.

General

When ordering copper-covered steel strand under this suggested specification, the size and strength rating of strand must be specified.

Variations

Each wire shall be accurate and uniform in diameter and of circular cross section. The variations in diameter shall not be more than 1½ per cent over or under the specified diameter.

Finish

Each wire shall be free from scale, splints, flaws, inequalities and all other imperfections. The wires shall fit snugly around the center wire.

Material

The individual wires comprising the strand shall be composed of a steel core with a copper covering permanently welded thereto. The wires shall be of such quality as to comply with the requirements for breaking strength of strand, as given in the following table:

Nominal Diameter	Number of Wires	Size of Individual Wires	Approximate Weight per 1000 Ft.	BREAKING STRENGTH, Min.	
				Standard	Extra-High Strength
5/16 in.	7	10 A. W. G.	209 lb.	5,600 lb.	....
11/32	7	9	267	6,790	....
3/8	7	8	332	8,400	11,460 lb.
7/16	7	7	418	10,160	14,420
1/2	7	6	526	12,600	18,200
9/16	7	5	663	15,400	22,930
5/8	7	4	836	18,550	28,980

(The breaking strength of the strand is taken as 90% of the sum of the breaking strengths of the individual wires).

Test of Breaking Strength

Samples shall be selected at random from finished strand and should be at least five feet in length, properly socketed and tested in a tensile testing machine. If the breaking strength of any test sample is found to be below the stated minimum value, tests shall be made upon two additional samples from the same coil or reel, and the average of the three tests shall be taken as the test value. Tests, wherein the strength is below specified minimum values, but which are obviously due to improperly applied sockets, shall not be considered.

When desired, tensile tests may be made on strand using gripping jaws of the testing machine in place of socketed specimens. If the strength values obtained meet the requirements of the table, tests on socketed specimens will not be required.

As an alternative to the above test of strand, breaking strength test may be made on each of the seven individual wires. Each wire shall have a strength of at least 15.9 per cent of the rated breaking strength of the 7-wire strand.

Elongation

The elongation shall not be less than 1 per cent in 10 in.

Brazes

Brazes in individual wires shall be made only in the finished size of wire and when ready for stranding. A separation of at least 150 ft. shall be maintained between any two brazes in the completed strand. Brazes shall be made in accordance with the best commercial practice, and the resistance to corrosion and tensile strength of the brazes shall be equal to that of the wire.

Pitch and Lay

The pitch of the strand shall not be less than 12 nor more than 16 diameters of the completed strand, and the lay may be either right or left, as specified by the purchaser. (The direction of the lay shall be considered that direction in which the helically placed wires cross over the axis of the strand as they recede from the observer.)

Conductivity

The amount of copper shall be determined by measuring the electrical conductivity of the wire. The volume conductivity of all seven wires shall average at least 30 per cent, and shall not be less than 27 per cent for any individual wire, being compared with the conductivity of the same size hard-drawn copper wire as a standard of 100 per cent.

Ferroxyl Test

The copper exterior on each wire shall be continuous over the whole length and circumference of the wire, and its thickness shall be ample and adequate to protect the center steel core from exposure where and when installed under corrosive and rusting atmospheric conditions.

In order to determine the necessary thickness of copper throughout the wire, the "Ferroxyl" test shall be made as described below, whereby successive concentric layers of copper are removed from the exterior of the wire. Samples of wire shall be selected at random and shall withstand such accelerated corrosion tests without exposure of steel. Any sample not passing this test shall cause rejection of the entire coil from which the sample was taken.

Each sample of wire to be tested shall, after being cleaned with carbon tetra-chloride or other grease remover, be held in a flame of a Bunsen burner for a length of time sufficient to bring it to a cherry-red heat. It shall then be withdrawn from the heat and allowed to cool in the air.

The sample shall then be placed in an 8 to 10 per cent solution of sulphuric acid, and the oxide thoroughly removed.

The sample shall again be placed in the flame of a Bunsen burner, and the test repeated as before. The above cycle of tests shall be repeated five consecutive times.

After removal from the sulphuric acid solution of the fifth cycle, sample shall be tested for exposed steel by immersing the sample in a Ferroxyl test solution which shall be made up as follows:

10 Grams C. P. Potassium Ferri Cyanide
20 Grams C. P. Sulphuric Acid
1 Liter C. P. water.
Dissolve cyanide in water.
Add acid slowly.

The presence of iron or steel is disclosed by a deep blue mark on the wire or marking in the solution. As this indicator is extremely sensitive, it is essential that the wire and any equipment used in making the test be perfectly clean. If in any test the presence of iron is indicated, the test should be repeated to ascertain whether the indication is due to exposed steel in the wire or to foreign iron rust, filings, scale or other irrelevant causes. The sample of wire shall be bent U-shape and, when immersed in the Ferroxyl solution, shall be held so that the exposed steel on the ends of the wire will not come in contact with the solution.

Test of Weld

The test of the weld between copper and steel shall be made on samples taken from wire rods from which the wire is cold-drawn, in order to observe specimens which have not been cold-worked. The specimens shall be broken by repeated bending, or by torsion, or by both.

The finished wire, or larger sizes of wire, may also be tested in like manner. Any indication of separation of the copper from the steel on any specimens shall cause rejection of entire lot.

Packing

The strand shall be furnished in coils or on reels in lengths as specified by the purchaser.

Marking

Each coil or reel shall be tagged or marked inside and outside with the purchaser's name, address, the purchaser's order number, the size, kind and net weight of the wire and the manufacturer's name.

Inspection

Inspection and acceptance may be made either at the point of manufacture or upon delivery of the finished product. The manufacturer shall give to the purchaser, or his representative, such access to his works during working hours as is reasonable and necessary to determine the suitability of the material to be supplied, and shall furnish all necessary apparatus, labor and other facilities for making the tests herein called for without cost to the purchaser. The manufacturer shall eliminate all strand that he considers defective according to this suggested specification, before offering any lot for inspection or before shipment. Neither inspection, waiving of inspection, nor the purchaser's acceptance shall release the manufacturer from obligation to furnish the material in accordance with this suggested specification.

Strand not conforming with this suggested specification shall be rejected, and the manufacturer shall furnish new strand complying with this suggested specification at his own expense, or shall allow credit for such rejected strand.

SOLDER

Scope

This suggested specification covers a lead-tin alloy used for solder metal.

General

Solder furnished under this suggested specification shall conform with the current specification of the American Society for Testing Materials. Quotations must be accompanied by samples, representative of the solder to be furnished under this specification.

Material

Each bar of solder shall be uniform in composition with the entire lot. The solder shall be made from new or properly refined metals. The alloy shall conform to the following requirements as to chemical composition:

Composition	String	Wiping
Tin	50%	40%
Lead (approximately)	50%	60%
Antimony (maximum)	0.12%	0.12%

The permissible variation plus or minus in the percentage of tin shall not be over 1 per cent of the tin contents specified above.

Packing

The solder shall be packed in tight wooden boxes containing 100 lb. net weight. Each box shall be marked with the purchaser's name and address, purchaser's order number, the amount and kind of solder, and the manufacturer's name.

Inspection

Inspection and acceptance may be made either at the point of manufacture or upon delivery of the finished product. The manufacturer shall give the purchaser or his representative such access to his works during working hours as is reasonable and necessary to determine the suitability of the material to be supplied, and shall furnish all the necessary apparatus, labor and other facilities for making the test herein called for, without cost to the purchaser. The manufacturer shall eliminate all solder that he considers defective, according to this suggested specification, before offering any lot for inspection or before shipment. Neither inspection, waiving of inspection, or the purchaser's acceptance shall relieve the manufacturer from the obligation to furnish solder in accordance with this suggested specification.

Solder not conforming with this suggested specification shall be rejected, and the manufacturer shall either replace such rejected solder with solder complying with this suggested specification at his own expense, or shall allow credit for such rejected solder.

POWER STATION CHEMISTRY—PART I

This, the initial report of the Chemists Subcommittee of the Prime Movers Committee, includes extensive bibliographies both on combustion chemistry and corrosion; a preliminary study of the fundamentals of lubrication chemistry, and a tentative standard method for quantitatively determining dissolved oxygen in boiler feed water supplies, raw water excepted.

The bibliography on combustion chemistry is preceded by a review of the developments in this field for the period 1926 *to* 1927.

The bibliography on corrosion has been indexed under the following headings: Theories and Factors, Gases and Pitting, Embrittlement, Corrosion Fatigue, Electrolysis, Oil Corrosion, Laboratory Tests, Prevention of Corrosion by Protective Coatings, Films and Tarnishing, Resistant Alloys, Boiler Water Treatment. The bibliography is current to 1928.

The report on lubrication presents an initial laboratory study on the chemistry of turbine oil. The program aims to supply to the user answers to the following questions:

1. *By what standard can oils be judged suitable for turbine use?*
2. *If turbine oils deteriorate during use, by what methods can the degree of deterioration be determined?*

It is suggested that the basis for judgment of an oil is a chemical one, and test data are cited showing that the criterion for determining the condition of an oil in service should include weekly tests for sludge, water, emulsion and neutralization number, and plotting this data in order to observe the trend of the curves. The change in chemical characteristics of the oil is apparently arrested if definite volumes of new oil, approximately 0.6 *per cent by volume, are added at regular intervals. The report concludes with a bibliography with an abstract of each article.*

A tentative method for determining dissolved oxygen in boiler feed water has been prepared, and is complete with definite sampling instructions, methods for preparing the necessary solutions, and the test procedure. The method may be applied both in the power plant and the laboratory. The subcommittee urges all station operators to follow the details exactly so that a definite standard may be established for correctly estimating the very low amounts of dissolved oxygen found in practice. This method was presented by the related Subcommittee of the Boiler Feed Waters Study Committee, and was tentatively adopted by the Chemists Subcommittee.

STUDY OF CHEMISTRY OF COMBUSTION—A REVIEW FOR YEARS 1926 AND 1927

A review of the publications and papers on the subject of combustion appearing during the more recent years indicates at once that this abundance of material may be classified under various categories, depending upon the phase of combustion with which it is concerned.

Study and research in this field has received a marked impetus in the last decade, stimulated to a great extent by problems of immediate interest encountered in the practical application of combustion phenomena. Numerous examples of such may be cited. A thorough study of explosive and detonative combustion is made necessary in order to prevent gas and dust explosions which so often result in loss of life. Catalytic combustion has been studied much more intensely since the advent of antiknock fuels into the sphere of internal combustion engines. In fact, internal combustion problems embrace a multitude of factors in regard to combustion such as ignition temperatures, flame propagation and flame travel, inflammability, detonation, etc. In order to explain these properties of combustible mixtures, the physical or organic chemist attacks these problems from his respective point of view and the physicist renders assistance through his knowledge of spectroscopy.

Along with these purely scientific and empirical investigations, a number of theories have been formulated which have served to stimulate further scientific research on combustion.

In this report, which attempts to supply a comprehensive study of the chemistry of combustion and closely related phenomena for the years 1926 and 1927, the material has been arranged so far as expedient under the various headings mentioned above.

Catalytic Surface Combustion

In the field of catalytic surface combustion, Bone[1] and his collaborators have been most prominent.

The more recent work comprises a study of the union of carbon monoxide and oxygen in contact with nickel, copper and their oxides as well as a gold surface, and the union of carbon monoxide and other gases with oxygen in contact with a fireclay surface at 500 deg. cent. Regarding the catalytic effect of a gold surface, Bone concludes that the results are explained best by assuming an activation of both gases through association with the surface. This activation is not confined to superficially absorbed gas films of monomolecular thickness, but extends to more deeply occluded gases. In the case of metallic nickel, its catalytic activity, which was enhanced by preliminary exposure to carbon monoxide or carbon

---

Publication No. 289-28, Serial Report, Prime Movers Committee.

monoxide-oxygen mixtures at 370 deg. cent., is attributed to the formation of a highly reactive surface film of nickel carbonyl or oxycarbonyl. Since the nickel oxide catalyzed the oxidation of carbon monoxide without any appreciable reduction, the catalytic effect is believed due to the formation of a film of active oxygen upon the surface acting as the effective oxidizing agent. In the case of metallic copper, the formation of a film of volatile copper-carbon monoxide complex greatly reduces its catalytic activity. In contrast with nickel oxide, the copper oxide was rapidly reduced by carbon monoxide in the absence of oxygen. However, the actual cause of the catalytic activity involves the condensation of a film of active oxygen at the surface of the oxide and this film additionally protects the catalyzing surface from reduction by the carbon monoxide.

Experiments with a fireclay surface at 500 deg. cent. shows that the rates of catalytic oxidation of hydrogen, carbon monoxide and methane decreased in the order named. It was found that the catalyzing power of the fireclay could be stimulated temporarily by previous exposure to the combustible gas and that this stimulus could be removed by exposing the surface to oxygen at the reaction temperature.

Bone also published a paper on the results of an exhaustive study of the catalytic combustion of carbon monoxide over catalysts of porous porcelain, granular copper oxide, nickel oxide, gold gauze and silver foil in the presence and absence of water vapor. With a progressive removal of moisture the immediate effect was always to increase the apparent catalyzing power of the surface, presumably by removing from it the film of water molecules that normally lags it. The ultimate effect, which is observed usually after a prolonged drying, is to diminish greatly or even stop completely the catalytic combustion.

Bone, Weston, Fraser and Newitt[2] recently published their results upon the combustion of well-dried carbon monoxide and oxygen mixtures. They found this mixture could be ignited by means of a fairly powerful electric spark, but that combustion was incomplete in most cases, due to the absence of the catalytic effect of water vapor. They concluded that there is some property of the electric spark, presumably its ionizing power, which, if only developed strongly enough, can overcome the high resistance of such an extremely dry mixture to ignition and explosion and by virtue of which it can compensate the system for the absence of water vapor. In a spectroscopic examination of the flames resulting from the combustion of these well-dried mixtures under initial pressures of 25 atmospheres and upward, evidence was found that the water vapor played the part of an oxidizer, reacting with the carbon monoxide to give carbon dioxide and hydrogen. Recent results have shown hydrogen to be more potent than its equivalent of steam as a promoter of the combustion of carbon monoxide.

Although the mechanism of the action exhibited by antiknock compounds is not yet definitely determined, it seems to be the general opinion that the antiknock compounds exert an effect which is decidedly catalytic in character. A very comprehensive survey involving an experimental and theoretical study of antiknock materials has appeared in Ind. Eng. Chem., Vol. 18, p. 334, (1926), under the joint authorship of Church, Mock and Boord. The antiknock properties of a considerable number of metallic organic and inorganic compounds were tested and referred to that of lead tetraethyl, its value being arbitrarily taken as 100. A sufficient number of tests were performed to show that anomalies often existed between the knock suppressing power of a compound when determined in a motor and in an open tube. In a study of the electrical conductivity of the cylinder gases as a function of detonation it was found that the conductivity or gaseous ionization decreased with decreasing detonation in internal combustion engines. The authors also advanced a chemical theory of antiknock materials and their action in suppressing detonation.

An attempt to explain the effect of antiknock compounds recently has been made in another direction. Lind and Bardwell[3] investigated the influence of diethyl selenium upon the rate of the slow oxidation of methane under the ionizing influence of alpha-radiation. Contrary to what might be expected, an acceleration rather than retardation of the rate was observed.

As yet there has been no theory advanced on the mechanism of the action of antiknocks and antidetonants which adequately accounts for all the observed facts. During the last two years a large number of papers have appeared bearing upon both experimental and theoretical aspects. Of the more noteworthy observed facts, there might be mentioned:

1. The decrease in the rate of oxidation of benzaldehyde by lead tetraethyl.[4]
2. The application of autoxidation and antioxygenic action to the problem of the mechanism of the action of antidetonants.[5]
3. The analytical determination of the antiknock property of a gasoline.[6]
4. An attempt to find a relation between the degree of ionization of organic compounds in flames and the amount of detonation in engines burning fuel containing them.[7] No simple relation was found.

Inflammability

Most of the recent work on the limits of inflammability of gaseous mixtures has been performed by Tanaka and Nagai.[8] They have studied the influence of ethyl bromide as well as other organic bromides, iodides, etc., upon the inflammability limits of hydrogen air mixtures. In addition, they investigated the influence of alkyl halides on the inflammability of various mixtures as well as the effect of pressure on the limits of inflammability and the average life period of activated molecules in combustion. In most cases the authors found that Le Chatelier's rule, which applies to the limits of inflammability of combustible mixed gas-air mixtures, was followed more or less accurately. The results of a study on the limits of inflammability of firedamp (methane) in atmospheres which contain black damp (nitrogen) have been published by Coward and Hartwell.[9] They concluded that the addition of moderate amounts of nitrogen to the air would not appreciably diminish the danger of a firedamp explosion under ground.

Ignition

Considerable work has been done by Wheeler[10] and his associates upon the physical conditions and environment affecting the ignition of combustible gas. Much of this work was carried out under the auspices of the Safety in Mines Research Board and was a study of the factors influencing the ignition of gas by momentary flames and hot wires.

In this same category might be mentioned the work done by Coward and Guest[11] on the ignition of natural gas-air mixtures by heated metal bars; and Brewer[12] on the ignition of carbon monoxide-oxygen mixtures by means of electric sparks.

In regard to ignition in homogeneous systems notable work has been done by Tanaka and Nagai[13] in studying the effects of antiknock substances such as diethyl selenide and tetraethyl lead upon the spontaneous ignition temperatures of various inflammable liquids. This work was extended to include a study of the effects produced by the addition of aromatic amines and pyridine, which also show an antiknock effect. Coward and Meiter[14] have published an account of a very comprehensive investigation upon chemical action in the electric spark discharge and the conditions affecting the ignition of methane oxygen mixtures. Walls and Wheeler[15] have made a similar study upon the ignition of paraffin-air mixtures by flames.

Flame Propagation and Flame Travel

Ellis and Wheeler[16] have been occupied with a study of the movement of flames in closed vessels. In the case of the combustion of carbon monoxide-air mixtures they found that the flame speed usually consisted of two phases: (1) A speed uniform from the center of the sphere outward to near the walls and (2) a decreased speed due to a compression of the exploded and unexploded gases.

Chapman and Wheeler[17] studied the effects produced by the shape of the vessel upon the flame speed in a mixture of methane and air. They found that constricting rings placed in the tubular combustion chamber increased the speeds up to a certain limit.

The mechanism of the uniform movement in the propagation of flame has been studied for methane-air mixtures by Coward and Jones.[18] Their results indicated that the speed was dependent upon the heat developed, the thermal capacity of the gases and the rate of chemical reaction.

Jones and Perrott[19] made a study of the amounts of oxygen necessary to propagate the flames in hydrogen, carbon monoxide, and methane-air mixtures. This research was performed with a view to its practical application to conditions existing in mines.

Ellis[20] reports a study of flame movement in a Safety in Mines Research Board publication.

Bone, Fraser and Winter[21] have made a study of flame speeds for mixtures of hydrogen, acetylene and ethylene with oxygen and applied the results to the supposed law of flame speeds. The laws appeared not to hold.

White[22] had an article upon the effect of pressure on the limits for the propagation of flame in ether-air mixtures.

Explosions and Detonations

Saunders[23] and his co-workers have described some work involving a study of ionization in exploding gaseous mixtures. They reached the conclusion that the electrical conductivity of the dry gases, *i.e.*, the degree of ionization was mainly thermal in character for carbon monoxide-oxygen mixtures and discovered that the addition of hydrogen or water vapor greatly increased the ionization during explosion. In a study of the explosions of methane-oxygen mixtures the maximum electrical conductivity was produced when the hydrogen was burned to water and the carbon to carbon dioxide. However, in the acetylene-oxygen mixtures the maximum conductivity was obtained when the carbon was burned only to carbon monoxide, and hydrogen going to water as in the former case.

Egerton and Gates[24] have published a paper on the detonation of gaseous mixtures of acetylene and pentane and one involving a study of detonation in gaseous mixtures at high initial pressures and temperatures.

Spectroscopy

Most of the special studies made upon the combustion of gaseous mixtures during the last two years has been in the ultraviolet region. Work has been done by Clark, Henne and Thee[25] on the ultraviolet spectra of motor fuel flames. The ultraviolet emission lines for lead constitute the most sensitive test for the presence of lead tetraethyl in fuels.

Bone and Newitt[26] obtained a collection of interesting data and photographs in a spectrographic investigation of the ultraviolet radiation from carbon monoxide-oxygen or air mixtures. These results were not interpreted.

Equilibrium and Velocity of Combustion Reactions

Probably the most important work in this field has been reported in a paper by Haslam, Mackie and Reed.[27] Therein they describe the results obtained on the effect of depth of fuel bed and rate of firing upon the heating value, cold gas efficiency and per cent steam decomposed in the manufacture of producer gas. With a fuel bed consisting of anthracite coal they found that an increase in depth and rate of firing produced a corresponding increase in the three latter factors.

Allner[28] in a paper on combustion velocity and equilibria in combustion gives a general discussion and summary of data on the various factors entering into gaseous combustion and their application to practice.

Goff[29] also published a study on the chemical reactions in the gas producer based upon the knowledge of chemical equilibrium on the constitution of gas mixtures.

In this connection, a paper by Leffler[30] on the reaction velocity between carbon dioxide and different species of carbonized fuel might be mentioned.

Additional papers have appeared which are concerned with the chemistry, both structural and reactional, of various fuels. Most of these are discussions and summaries of knowledge obtained at some previous period and do not describe original research. A list of these papers will be found below.

There are a number of other papers related to combustion which do not fall naturally into the categories listed above but which deserve special mention.

A paper by Bone, Newitt and Townsend[31] describes the effect of argon and helium as diluents upon the explosions of hydrogen and carbon monoxide detonating gas mixtures. Helium would seem to influence the explosion reaction in a specific manner.

Harrison and Baxter[32] found that, in the combustion of carbon monoxide, the presence of small amounts of hydrogen produce an effect all out of proportion to the amount present. One-half per cent was found to alter the process completely.

Maxwell, Payman and Wheeler[33] have published the results of a study upon the combustion of complex gaseous mixtures such as (1) hydrogen, (2) three parts hydrogen plus one part carbon monoxide, (3) equal parts of hydrogen and carbon monoxide, (4) one part hydrogen plus three parts carbon monoxide, (5) carbon monoxide with air.

Papers relating to combustion control, calculations and computations as well as those classed under the heading of miscellaneous will be found listed below.

LUBRICANTS AND INSULATION

Scope

The two major questions regarding turbine lubrication are: (1) By what standards can oils be judged as suitable for turbine use? (2) If turbine oils deteriorate through use, by what methods can the degree of deterioration be determined? It is intended that the work of this Section will result in satisfactory answers to these two questions, and this report is intended merely to give the progress of the work to date and offer tentative conclusions.

Conclusions

The judgment of the suitability of oil for turbine use must be based upon the fundamental chemical characteristics of petroleum rather than upon the ordinary semi-chemical properties indicated by the tests now in common use. What those characteristics will be has not yet been established, but sufficient data are at hand to indicate that suitable tests may be developed.

It is still believed to be a question whether a suitable oil deteriorates in lubricating and chemical quality. Tests have indicated that after a service period estimated as 16,000 hours no material change is produced in those qualities of the oil usually taken as criteria of fitness.

However, during such period of usage certain products develop in the oil, such as sludge, emulsion, water and acidity. Such products may be measured and removed from the oil, and the degree to which they are removed governs the degree to which their development continues. The continued development and removal of such products points to the ultimate consumption of the oil through chemical change. These products introduce undesirable operating conditions and it has been common practice to consider their appearance as evidence of the deterioration of the oil. Our tests have shown that with all surrounding conditions remaining constant the development of these products takes place in cycles; they do not completely disappear, but they appear alternately in large and small amounts. It would also appear that the frequency of these cycles is from 4 to 6 weeks, or sometimes longer. From such observations it would appear that tests at least once a week are desirable if the true condition of the oil is to be found and that tests at less frequent intervals are quite likely to result in false conclusions. Our observations have been that the determination of the amount of sludge in such tests is a criterion by which to judge the condition of the oil. The amount of sludge may be determined in a number of ways: (a) By observation and photography at 100 magnifications, (b) by direct weighing, and (c) by volumetric measurement with the aid of a centrifuge.

In addition to these tentative conclusions pertaining to the two major questions, it is possible to submit certain facts relative to the use of so-called anti-oxidants in turbine oil. It is assumed, and the data quite generally indicates, that the development of objectionable products in turbine oil is a direct function of oxidation. Such being the case, the introduction of a compound designed to react with the oxygen which comes in contact with the oil, should, in a measure, prevent or retard the oxidation of the petroleum hydrocarbons. In the two cases examined to date such is the case. When an oil has a tendency to form oxidation products—sludge—an anti-oxidant will prevent it, but will in turn form oxidation products of its own of a lesser magnitude than those of the petroleum hydrocarbons. With an oil showing little or no tendency to sludge the use of anti-oxidants shows no advantage.

Test Procedure

The tests were carried out in a Funk Sludging Machine. Thirty-two quarts of oil and three quarts of water constituted the charge to be tested. Samples were taken hourly. The tests made are defined as follows:

A. **Sludge and Emulsion.**—Sludge was defined as that material developed in the oil during the test, and which was insoluble in the oil at room temperature, and is the same as that developed in the oil during use through the action of air, heat and water. It was further defined as being insoluble in gasoline at room temperature, and free of oil and moisture at 212 deg. fahr. Emulsion was defined as being that material which separates upon centrifuging and exists between the water and the oil layer in the centrifuge tube.

The amount of sludge and emulsion was determined as follows: Before the different phases of the oil-water mixture, drawn from the machine as a sample, had an opportunity to separate, 100 c.c. was poured into each of two 100 c.c. centrifuge tubes. These volumes were then centrifuged for 30 minutes at 1000 r.p.m. At the end of that time the volume of emulsion was read and recorded. The clear oil was decanted and reserved for the acidity determination. The remaining solution and sludge were filtered through a dry, weighed Gooch crucible, washed thoroughly with gasoline and dried for 1 hour at 212 deg. fahr. The increase in weight of the crucible was taken as the amount of sludge.

B. **Acidity.**—The acidity was defined indirectly as the amount of potassium hydroxide, expressed in milligrams, required to neutralize one gram of oil when used as the titrating reagent in an alcoholic solution and in the presence of phenolphthalein as the indicator. About 20 c.c. of oil was used for this test.

C. **Viscosity.**—The viscosity at 100 deg. fahr. was determined by every fourth sample with the Saybolt Universal Viscosimeter.

D. Such other tests as were performed on the samples before and after sludging were done in accordance with standard methods.

Regarding the significance of these tests as they apply to the fitness of oils for turbine lubrication, the following may be said: The test in the sludging machine is capable of distinguishing between a rapidly oxidizing oil and one that oxidizes at a slower rate. Such information is certainly of prime importance to the user of this type of oil, and a continued critical study of the changes the oils undergo in this test may reveal the nature of the hydrocarbons chiefly responsible for the sludging trouble. At present a study is under way to establish the fundamental differences between the two untreated oils discussed herein. Both are well-known oils, actually giving fairly satisfactory service in use, yet each possesses distinct chemical properties which must to a large degree be responsible for the formation of oxidation products developing to different degrees in each. Further, such properties undoubtedly govern the degree of satisfactory service experienced. By continuing along this line, it is believed the desired end will be reached.

The significance of these tests as applied to the use and the testing of oil while in service lies chiefly in the fact that they illustrate how unreliable spot or periodic tests may be when the results are used to determine the general condition of the oil. The true condition of an oil in service may be ascertained only by following its changes and the conditions to which it is subjected by simple tests at frequent intervals.

Although it is not the intent of this report to discuss methods of handling and reconditioning the oil, the work just finished has developed one very important point: as long as regular definite additions of what may be termed "sweetening" oil are made to the volume in service, the oil remains in apparent excellent condition. Although this practice is in vogue at present, it is doubtful if it has a very definite improvement motive behind it. From the results shown it would appear that 0.6 per cent by volume of fresh oil added to the batch in service at regular intervals would keep the oil in good shape indefinitely. Whether this specific amount of sweetening oil is of particular importance, or whether it must, as was the case in our tests, be accompanied by the withdrawal of an equal amount of the oil in service cannot be stated. Should such be the case, a satisfactory method of handling the situation could be developed and a general improvement in service be experienced.

Too little as yet has been done in the application of anti-oxidants to the field of lubrication to warrant making any definite statements. It appears that direct oxidation of the petroleum hydrocarbons is retarded, but whether other oxidation developments equally undesirable occur has not been established.

It should be borne in mind that the conditions imposed on the oil in these tests were extremely severe with respect to water and oxygen. However, in service, temporary conditions of equal severity may occur, and the effect on the oil examined under those conditions, may be as apparently serious as that observed here. Such effects are temporary, however, and need not be cause for dumping a large quantity of oil. With judicious care these effects may be overcome and the oil quickly restored to its normal condition.

Bibliography Abstracts

The following bibliography abstracts are submitted:

1927

EVALUATION OF TRANSFORMER OILS. By J. G. Ford, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. J. Ind. Eng. Chem., Vol. 19, Oct., 1927, pp. 1165 to 1171.

Sludging is caused by oxygen being in continual contact with oil. Oil readily dissolves oxygen. Heat and light accelerates oxidation of oil. Some oils, chiefly the water-white type, form little or no sludge, but produce on oxidation considerable amounts of organic acids. Mineral oils slowly oxidize even at room temperature, in the presence of light, moisture and oxygen. Two criticisms of the majority of oil tests are that the time consumed in making them is disadvantageous, and it is difficult to reproduce results.

Unsaturated hydrocarbons play an important rôle in the oxidation of oils. There is a definite relationship between the quantity of sludge formed and the unsaturated hydrocarbons as measured by 95 per cent sulphuric acid absorption. The oxidation of saturated hydrocarbons is retarded by the presence of unsaturated compounds. Small amounts of unsaturated hydrocarbons retard oxidation only temporarily, and finally large quantities of sludge are precipitated. With oils containing over 5 per cent unsaturated hydrocarbons the quantity of sludge formed appears to be independent of the base of the oil. Although the method for the determination of naphthenes is not entirely free from error, it is of value for determining the approximate source of an oil and for showing how it will act under certain conditions. High molecular weight naphthene hydrocarbons do not appear to be as sensitive to oxidation as those of low molecular weight. Mixtures of high molecular weight naphthene with paraffin hydrocarbons give an oil with high resistance to oxidation. No general rule can be given concerning the effect of different temperatures on the rate of oxidation of different oils. Temperatures other than operating temperatures will give false results with certain oils.

Methods are described for determining naphthene and paraffin hydrocarbons and for the determination of unsaturated hydrocarbons. Data are given showing the effect of acid on precipitation of sludge, also the effect of temperature on the rate of oxidation.

EVALUATION OF TURBINE OILS. By T. H. Rogers and C. E. Miller. Ind. Eng. Chem. 19, 308-12 (1927). Abstr. Chem. Abstracts, Vol. 21, 1927, p. 1346.

A stability test has been developed for the evaluation of turbine oils in which moist O_2 is passed through the oil at 100 deg. cent. in the presence of iron. Determinations of the acidity and demulsibility of the samples taken periodically along with the sludging time serve as a measure of the degree of oxidation and its effect on turbine service. By comparative turbine test runs it has been established that this stability test substantially duplicates the behavior of oils in a dry turbine.

REFINING TRANSFORMER AND TURBINE OILS. By N. Butkov Neftyanoe Khozyaistvo 10, 388-92 (1926). Abstr. Chem. Abstracts, Vol. 21, 1927, p. 2554.

To identify the anti-oxidizing agent of the petroleum-resins, O_2 was passed at 120 deg. cent. through a transformer oil to which naphthalene, phenol, aniline, a-naphthol, anthracene and a-naphthylamine had been added. The first three substances had little effect but the last three had a strong anti-oxidizing action. The presence of 1.5 per cent of a-naphthylamine reduced the acidity after passing O_2 for 60 hr. from 21.05 to 0.18 mg. of KOH. If the acid constituents be removed from acid-refined oil by SiO_2 gel instead of alkali, the stability of the oil is improved because of the absence of Na salts of the organic acids. The tendency of the paraffin wax to oxidize is increased by treatment with strong alkali solutions after oleum refining. The treatment of the oil with SiO_2 gel occupies 1.5 hr. The gel absorbs 1 per cent of sulphuric acids, which may be recovered, and the gel may be regenerated by heating. It is proposed to substitute H_2SO_4 in refining by the O_2 of the air. On passing air at 100 deg. cent. for 12 hr. and treatment with 20 per cent of SiO_2 gel a light oil of d.0.885 and acidity 0.02 was obtained. On passing O_2 at 120 deg. cent. for 36 hr. the acidity was 0.03. Pb vessels cannot be employed. An increase of pressure of the air to 2 atmosphere shortens the process by 3 hr. Turbine oil treated by this process is less liable to emulsify.

REPORT OF SUBCOMMITTEE XI ON TURBINE OILS. By James T. B. Bowles. Proc. A. S. T. M. 26, pt. 1, 370-380 (1926). Abstr. Chem. Abstr., Vol. 21, 1927, p. 1346.

Collaborative results in the A. S. T. M. steam emulsion test and on the Herschel demulsibility test showed a considerable variation between different laboratories in both methods, but the variation was clearly much less with the steam emulsion test (about 15 per cent average departure from the mean) than with the Herschel demulsibility test (over 40 per cent average departure from the mean). The results are interpreted as proving that the former gives more concordant results than the latter. Collaborative results are given of the Funk sludging machine tests after running 50 hr. with the addition of H_2O, showing fair agreement between all the laboratories except one. The test is not intended to take the place of the steam emulsion or of the Herschel demulsibility tests, but was developed to test out large samples of oil under conditions approximating those found in a turbine. The results obtained show only a fair agreement and finer gradation is obtained with the steam emulsion test. Detailed directions are given for running the 50 hr. test with the Funk sludge accelerator.

R. T. HASLEM and P. K. FROLICH. Deterioration of Mineral Oils I. Mechanism of Oxidation and Action of Negative Catalysts as Determined by a Dynamic Method. Ind. Eng. Chem. 19, 292-6 (1927). Abstr. Chem. Abstr., Vol. 21, 1927, p. 1345.

H. and F. oxidize medicinal oil in a current of air or O_2 at 130 deg. and 140 deg. cent. After a period of inhibition, oxidation starts, as shown by color, viscosity, acidity and total O_2 absorbed. The mechanism of oxidation is discussed, together with the action of several catalysts.

G. BAUM. Methods of Investigating Transformer, Switch and Turbine Oils. Z. Agnew. Chem. 39, 473-5, 1926. Also in Petroleum Z22, 562-3, 1926, and Abstr. Chem. Abstr., Vol. 21, 1927, p. 1005.

The methods of test are discussed critically. B proposes that the A. E. G. oxidation test (Na_2O_2) be compared with the Schwarz-Marcusson (50 hr. at 120 deg. cent.) and the umpire method (70 hr. at 120 deg. cent., and 2 bubbles of O_2 per second) in the hope that the simpler method (Na_2O_2) may be proved useful. Oils that form less "tar" than the allowable quantity frequently give unsatisfactory service. More significant tests must be devised. The proposal of von der Heyden and Typken that the sludge formed be considered a criterion of the quality of the oil is accepted as promising, but air should be used instead of oxygen, and only the insoluble sludge should be considered. Sludge precipitated by petroleum ether should be ignored. Oils should be accepted for the uses in question only when they are low in "unsaturated constituents," as determined by the following test: 5 c.c. of oil and 5 c.c. of H_2SO_4 (1.84 sp. gr.) are put into a graduated centrifuge bottle (15 c.c.) and are mixed by air bubbles for 0.5 hr. through a glass capillary. After centrifuging at 3000 r.p.m. for 10 min. the increase of volume of the aid layer is determined. An increase of 5 per cent is the maximum allowable. Discussion of the address is appended.

1926

THE USE OF ANTIOXIDANTS IN OILS. Anonymous. Rubber Age (NY) 20, 27, 30, 1926. Abstr. Chem. Abstracts, Vol. 20, 1926, p. 3801.

Aldol—a-naphthylamine ("agerite") has already proved itself of great value in retarding the oxidation and therefore the deterioration of vulcanized rubber. Similarly, its addition to mineral oils, in which it is soluble, stabilizes the oils so that their electrical resistivity after prolonged heating is far higher than the corresponding untreated oils under the same conditions.

L. A. GLOUCHMAN and N. L. ALCHENA. The Konradson Demulsification Test for Turbine Oils Azerbaidj Neft., Choz. 51, 75-7 (1926). Also in Chimie et Industrie 16, 58 (1926), and Abstr. Chem. Abstr., Vol. 20, 1926, p. 3801.

Pass steam for exactly 10 min. into a 250 c.c. graduated cylinder containing 20 c.c. of H_2O and 100 c.c. of oil, place in a water bath at 55 deg. cent. for 1 hr. and note the amount of H_2O (either clean or milky) of emulsion and of oil, and the H_2O content of the oil. With a given oil the rate of separation of the emulsion may vary, but the final result is constant; the H_2O content of the separated oil cannot always be determined with the desired degree of accuracy; on the whole, the method yields fairly accurate results. Application of the test to turbine oils prepared by treating ordinary machine oil with 1, 2 or 3 per cent of SiO_2 gel showed that the oil was improved and did not give any emulsion. The method is suitable for adoption as a standard test, except that it is unnecessary to determine the H_2O content of the oil, and the height of the emulsified layer is the only important consideration.

SIROZI HATTA. Effects of Tetraethyl Lead Upon Deteriorations of Turbine Oils. J. Soc. Chem. Ind. Japan, Vol. 28, 1346-52 (1925). Abstr. Chem. Abstr., Easton, Vol. 20, 1926, p. 816.

On the assumption that the deterioration of turbine oils is due mainly to the oxidation of the components of the oils by the action of heat and air, Et_4Pb was used as an anti-catalyser of the oxidation. 0.05, 0.1 or 0.2 per cent of Et_4Pb was added to pure oils and kept at 120 deg. cent.;

moist O_2 was passed in at the rate of about 150 bubbles per minute. Samples were taken at definite time intervals for testing color, specific gravity, viscosity, acid and saponification value, amount of sludge and the Herschel di-emulsivity. When an oil of the paraffin series was used, the darkening of the color, the sludge formation and the deterioration of di-emulsive power were distinctly decreased by the presence of Et_4Pb. The specific gravity, viscosity and acid and saponification values of the oil were, however, independent of the presence of Et_4Pb, all increasing gradually.

As to oils of the naphthenic series, the result was of an opposite nature, except that the darkening of the color was retarded; the specific gravity, acid and saponification values and the sludge formation were all distinctly increased by the presence of Et_4Pb.

F. Schwarz. New Method for Preparation of Valuable Mineral Oils, Especially Transformer and Turbine Oils. Petroleum Z22, pp. 576-8, 1926. Abstr. Chem. Abstr., Vol. 21, 1927, p. 1182.

The treatment of distillates, etc., by means of H_2SO_4 is discussed.

1925

Hans Staeger. Indice de Goudrionnification et Specifications Des Huiles Utilisees pour Les Transformateurs Et Les Turbines a Vapeur. (Brown Boveri Cie. Revue, Baden, Annee 12, 1925, pp. 131-135, 150-153.)

This article seeks to show that the tar figure is not a suitable basis for the comparison of transformer oils since it takes into account only the acidity of oil under given conditions and does not indicate the various reaction products resulting from the decomposition of the oil.

A. Salathe. Examination of a Turbine Oil Sludge. Ind. Eng. Chem. 17, 414-15 (1925). Abstr. Chem. Abstr., Vol. 19, 1925, pp. 414-15.

A sludge from Sterling Quality Turbine Oil used in a 25,000-kw. turbine contained 42.5 per cent water and 13.6 per cent acids (aliphatic and naphthenic, calculated on an oil-free basis). Treatment of the water from the sludge with I_2 and warming in the presence of sufficient Na_2CO_3 to produce alkalinity caused precipitation of iodoform, proving presence of acetaldehyde. The high saponification value obtained showed presence of acids, esters and soaps. Oxidation as a cause of sludging is indicated.

1924

Hans Staeger. Ueber den Katalytischen Einfluss von Metallen Auf Mineralöle (Schweizerische Elektrotechnische Verein Bulletin, Zurich, Jahrgang 15, 1924, pp. 93-106. Abstracted in Electrical World, New York, Vol. 83, 1924, p. 1016. Science Abstracts, London, Vol. 27-B, 1924, p. 464. Chemical Abstracts, Easton, Vol. 19, 1925, p. 724.

Bare copper, brass, tin and zinc accelerate sludging of oil considerably. The action depends upon the proportion between the surface of the submerged metal and the volume of oil except in the case of aluminum, tin, nickel, iron—with which metals the oxidation at the zone of immersion is of importance. Lead, copper and zinc are eaten away by the generated asphaltogenous acids. The presence of lead liberates a highly oxidizing product of resinous character. The data are given in curves, tabulations and microphotographs.

T. S. Sligh, Jr. An Oxidation Method for Measuring the Stability of Mineral Oils—A. S. T. M. Proceedings, Philadelphia, Vol. 24, Part II, 1924, pp. 964-972, discussion pp. 973-974.

The oxidation methods proposed in this paper for obtaining knowledge of the sludging characteristics of oils are intended as standardized tests which may be applied to laboratory investigations. The tests consist essentially in distinguishing between various classes of oxidation products and a sludging number is assigned—depending upon the amounts and proportions of products formed.

Evert Norlin. Undersokningar over Transformatorolior Metoder for Bestamning av Transformatorolyors Bestandighet Mot Luftoxidation (Stockholm), 1925, 46 pages. Sweden-Statens Provninganstalt Meddelande 25.

In this paper a report is given on the investigations made for the purpose of elaborating the chief methods of testing the resistance of transformer oils to oxidation by the air, viz., methods of testing tar value, asphalt value, formolite value and iodine value. The results obtained with the Kissling and Brauer tar value tests are compared and a standard method devised. The asphalt value (Michie) test was adopted with slight changes.

National Electric Light Association. Prime Movers Committee—Report 1924. Lubrication (N. E. L. A. Proceedings, New York, 1924, pp. 1426-1438).

Information is given as to methods of making tests for the oxidation, acidification, emulsification and sludging of turbine oils. Laboratory data is presented in graphic form to show the relation of water to acidification, oxidation and sludge formation; the effect of air and water on oxidation and the relation of the amount of water present to emulsibility. A "sludge accelerator" is described and a comparison is made of the results obtained with this device as against the results obtained in actual practice.

Hans Von Der Heyden and Kurt Typke. Einwirkung Verschiedener Seifer auf Transformatorenöl Petroleum, Berlin, Jahrgang 20, 1924, pp. 857-858. Abstr. Chem. Abstr., Easton, Vol. 18, 1925, p. 3474. Soc. of Chem. Ind. Journal, London, Vol. 43, 1924, pB-624.

After heating samples of transformer oil with lead, iron, copper, sodium potassium, magnesium, calcium and aluminum oleates and lead, iron and copper stearates, the following properties were determined: Color, precipitate, viscosity, ash content, acid number and tar number.

Frank Fritz. Beobachtungen über die Ursachen der Veränderung der Schmier und Isolieröle im Gebrauch. Petroleum, Berlin, Jahrgang 20, 1924, pp. 1488-1493. Same, Condensed, in Der Praktische Maschinen Konstrukteur, Berlin, Jahrgang 57, 1924, pp. 579-580. Abstracted in Chemisches Zentralblatt, Berlin, Folge 6, Jahrgang 6, 1924, p. 2626.

Discusses in a general way the function of oil in transformers, the causes of sludging and acid formation, and methods of maintaining dielectric strength.

Four stages in turbine oil decomposition:

1. Oxygen combines with oil and forms acids and secondary decomposition products.
2. Formation of metal salts from these acids.
3. Formation of high molecular weight oxygen addition—compounds of hydrocarbons.
4. Decomposition of high molecular weight compounds into low molecular weight compounds.

In a decomposing oil:

1. The specific gravity and flash point go up.
2. The viscosity increases.
3. The saponification value increases.
4. The tar number increases rapidly and the iodine number decreases.

TENTATIVE METHOD FOR DETERMINATION OF DISSOLVED OXYGEN IN BOILER FEED WATER—ISSUED APRIL, 1928

Scope

The presence of dissolved oxygen in water used for boiler feed is objectionable, since it increases the corrosive properties of the water. It is essential in steam-station operation that the dissolved oxygen content of the feed water be kept as low as possible. In order to control the dissolved oxygen, tests should be made at frequent intervals.

Application of Test

The application of the Winkler method, herein described in detail, is intended for use on all boiler feed water supplies except raw water.

If organic matter, nitrates or iron salts are present in appreciable amounts the Rideal-Stewart method (appearing in Standard Methods of Water Analysis A. P. H. A., 6th Edition, 1925) should be applied.

After further investigation it may be possible to indicate the permissible amounts of organic matter, nitrites or iron salts under which the method outlined may be employed.

Description of the Winkler Method for Determining Dissolved Oxygen

The Winkler Iodimetric method depends upon the liberation in the solution of an amount of iodine exactly proportional to the amount of oxygen dissolved. Chemically, it amounts to the oxidation of the manganous chloride solution to manganic acid by the oxygen present, and a subsequent reduction of iodide by the manganic acid. The starch indicator indicates the presence of iodine, and the standardized solution of sodium thiosulphate has a definite iodine absorbing value. The calculations by the formula are in terms of oxygen, but the intermediate steps are computed in terms of iodine. The reactions involved are given in Table II.

Reagents

1. **Manganous Chloride**—Dissolve 425.5 grams of crystalline manganous chloride C.P. $(4H_2O)$ in 1000 c.c. of distilled water.

2. **Alkaline Potassium Iodide**—700 grams of potassium hydroxide c.p. and 150 grams of potassium iodide c.p. are dissolved separately in distilled water and the mixture diluted to 1000 c.c.

3. **Sulphuric Acid**—Equal volumes of c.p. concentrated acid (sp. gr. 1.84) and distilled water.

4. **Starch Solution**—Dissolve 5 grams of Litner's Soluble Starch in 50 c.c. of distilled water to make a thin paste, and then pour into 200 c.c. of boiling distilled water and continue boiling for 4 or 5 minutes. When cold add a few drops of chloroform and keep this solution in a dark glass stoppered bottle. Starch solution does not keep well and should be made up fresh every week.

5. **Sodium Thiosulfate: 0.025 N solution**—Dissolve 6.205 grams of chemically pure recrystallized sodium thiosulfate in distilled water and dilute the solution to 1000 c.c. with freshly boiled and cooled distilled water. Each c.c. is equivalent to 0.2 mg. of oxygen, or to 0.1395 c.c. of oxygen at 0 deg. cent. and 760 mm. pressure. Inasmuch as this solution is not permanent, it should be standardized weekly against a 0.025 N solution of Potassium Dichromate or 0.025 N solution of Potassium Permanganate. If special investigations are being made, the thiosulfate should be calibrated daily.

[NOTE: When facilities for the preparation of the above reagents are not available, they can be purchased from any reliable chemical supply house.]

Collection of Sample

Water supplies in excess of 125 deg. fahr. and above atmospheric pressure shall be cooled through

TABLE II

REACTIONS OF WINKLER TEST FOR DISSOLVED OXYGEN

(1)	$MnCl_2$ Manganous Chloride	+	2 KOH Potassium Hydroxide	=	$Mn(OH)_2$ Manganous Hydroxide	+	2 KCl Potassium Chloride		
(2)	2 $Mn(OH)_2$ Manganous Hydroxide	+	O_2 Oxygen	=	2 H_2MnO_3 Manganous Acid				
(3)	2 KCl Potassium Chloride	+	H_2SO_4 Sulfuric Acid	=	K_2SO_4 Potassium Sulfate	+	2 HCl Hydrochloric Acid		
(4)	$Mn(OH)_2$ Manganous Hydroxide	+	H_2SO_4 Sulfuric Acid	=	$MnSO_4$ Manganous Sulfate	+	2 H_2O Water		
(5)	H_2MnO_3 Manganous Acid	+	4 HCl Hydrochloric Acid	=	$MnCl_2$ Manganous Chloride	+	3 H_2O Water	+	Cl_2 Chlorine
(6)	2 KI Potassium Iodide	+	Cl_2 Chlorine	=	2 KCl Potassium Chloride	+	I_2 Iodine		
(7)	2 $Na_2S_2O_3$ Sodium Thiosulfate	+	I_2 Iodine	=	$Na_2S_4O_6$ Sodium Tetrathionate	+	2 NaI Sodium Iodide		

a copper coil condenser, throttled at the discharge end to room temperature.

A narrow-necked glass stoppered bottle of 250 to 300-c.c. capacity is satisfactory. To the end of the sample connection attach, by means of heavy walled rubber hose, a glass tube, which will permit filling the bottle by displacement of the air and water by overflowing. The minimum rate of filling should be 250 c.c. per 30 seconds, and the sample bottle should be permitted to overflow not less than 5 minutes. This procedure insures the complete removal of air in the bottle and subsequent solution in the water of such air. Make certain that the sample line from the source of sampling to the bottle has been freed of air bubbles and deposits by a strong flushing of the line. After the water has been displaced in the specified time, the glass tube admitting the water is removed and the glass stopper quickly inserted in place to prevent exposure of the sample to air. Make certain that no air space is left between the stopper and water. The glass stopper should be ground to a point or cone to eliminate trapping of air.

The next step of adding the reagents should proceed immediately.

Adding Reagents

Remove the stopper from the sample bottle and add immediately 2 c.c. of Manganous Chloride and 2 c.c. of Alkaline Potassium Iodide in the order mentioned and quickly replace the stopper. The pipettes used to deliver these reagents should extend to the bottom of the bottle, and the additions made in sequence with individual pipettes should be rapid. A short length of rubber tubing should be attached to the upper end of the pipettes to reduce the possibility of drawing the solution into the mouth. Do not expel solution by breath.

After the addition of the Alkaline Potassium Iodide replace the stopper, mix by shaking and *permit the precipitate to settle.* Then add 2 cc. of sulphuric acid and mix by shaking.

The procedure to this point must be carried out in the field, but after the acid has been added and the stopper replaced, the rest of the test shall be performed as soon as convenient, preferably within one hour.

Titrating Sample

Measure 250 c.c. of the sample and transfer to a 300 c.c. porcelain casserole. (The entire sample may be conveniently transferred and titrated if the volume of the sample bottles are previously determined).

Titrate the sample with 0.025 N Sodium Thiosulphate until the solution becomes a pale yellow color, then add 3 c.c. of the starch solution and titrate until the first disappearance of the blue color.

If the sample contains oxygen in excess of 0.5 c.c. per liter, the water will have a decided yellow color.

If zero or only traces of oxygen, the water will not appear yellow. The starch solution should then be added, and if any blue color appears thiosulphate should be added until the blue color disappears. The difference between the initial and final readings of the burette will be the number of cubic centimeters of thiosulphate used, which is proportional to the amount of oxygen present.

Calculations

If 250 c.c. of water were titrated, the calculations will be as follows:

$$\frac{1000}{250} \times (\text{c.c. of 0.025 N. Thio.} \times 0.1395) =$$

cubic centimeters of oxygen per liter standard condition (0 deg. cent. and 760 mm.). Express individual results to the second decimal place. Report values below 0.03 c.c. as "trace."

Notes When Making This Determination

(1) When the manganous chloride and alkaline potassium iodide are added a white precipitate will be noticed (manganese hydroxide).

(2) If oxygen is present, a brown colored precipitate will be noticed which is manganous acid, depending upon the amount of oxygen present.

(3) The addition of the sulphuric acid dissolves the brown precipitate and sets free an amount of iodine equivalent to the quantity of oxygen in the sample.

(4) The solution at this time will be yellow in color; the depth of color depending upon the amount of oxygen present.

(5) If oxygen is present and starch is added to the solution at this stage, the color will change to a deep green or blue color, depending upon the amount of iodine (oxygen) present.

Tolerance

With care the above procedure will give reproducible results as low as 0.03 c.c. of oxygen per liter.

POWER STATION CHEMISTRY — PART II

Abstract

This report of the Chemists' Subcommittee of the Prime Movers Committee includes a non-technical review of water treatment for steam generation. The committee has adopted as standard procedure the reporting of water analyses in ionic form, and expressed in parts per million by weight. The reactions involved in water treatment calculations are presented in ionic form, and a procedure is included for calculation of water reagent requirements. The presentation of the subject in ionic form departs from previously published methods. Attempts to visualize water composition by the use of hypothetical or so-called probable combinations is made more difficult by the increasing use of arbitrary conventionalities, which have no basis on fundamental data.

A contributed statement discusses a graphic method of controlling the treatment in a Lime Soda system. The committee publishes an individual member statement on a laboratory study of turbine oil, using a Funk sludging machine.

Approved test methods for judging the quality of turbine oils are presented under Recommended Test Procedures. The tests will serve to establish variations in various shipments of the same trade name of turbine oils, and a selected few will serve in a measure to show the rate of alteration an oil undergoes in service. The tests alone are not suitable for determining the comparative desirability of different brands of new oils for turbine lubricating service.

The report emphasizes the desirability of making tests for the Hydrogen Ion Concentration in water supplies as one of the factors to be considered in the corrosiveness of the water, and statements of the significance of the Hydrogen Ion Concentration have been included both as committee and manufacturers statements.

Individual members have submitted statements for plant use, one on the graphical estimation of various alkalinities in water, the other, a plant control test for estimating phosphates in boiler water.

A manufacturer's statement on equipment for the electrometric determination of Hydrogen Ion Concentration and direct reading of the conductance of water concludes the report.

WATER TREATMENT FOR STEAM GENERATION

Committee Statement

Scope

The report discusses the major mechanical and chemical processes for treating water for steam generation. The mechanism of the reactions in the chemical processes is detailed both in molecular and ionic form. The ionic form, adopted by the committee, is used in the water analysis statement and in the treatment calculations.

Processes

The processes in use may be classified as:

A. *Non-chemical*
  1. Sedimentation
  2. Filtration
  3. Evaporation
  4. Deconcentration by blow down
  5. Deaeration

B. *Chemical*
  1. External
    a. Lime-Soda Ash
      Intermittent and Continuous—cold
      Continuous—hot
    b. Lime—Barium
      Intermittent and Continuous—cold
    c. Lime—Sodium Aluminate
      Intermittent and Continuous—cold
      Continuous—hot
    d. Base Exchange (Zeolite)
      Continuous—cold
  2. Internal
    e. Hydroxides and Carbonates
    f. Aluminates
    g. Phosphates
    h. Foam Preventives

Non-Chemical Processes

The non-chemical processes are not discussed because in most instances mechanical construction and operation constitute the major problem. Quite often water receives chemical treatment previous to filtration or evaporation. These cases are similar to those covered under External Chemical Treatment.

The optimum conditions for steam generation are the production of clean steam, free from both entrained solids and gases originating either in the feed water or formed by decomposition of treating reagents in the boiler. Mechanical methods are available for the removal of dissolved oxygen and free carbon dioxide. Partly combined carbon dioxide (HCO_3) requires chemical treatment for its complete removal before the water enters the boiler, since only partial removal is made by mechanical processes, such as deaerators and heaters.

Publication No. 289-114, Serial Report, Prime Movers Committee.

CHEMICAL PROCESSES

External Chemical Treatment

The chemical methods of water treatment involve reagent additions to prevent the formation of scale, and to minimize priming and foaming within the boiler. The formation of scale is prevented by eliminating the scale forming constituents as insoluble solids, prior to admission of the water into the boiler.

The scale-forming ions are calcium and magnesium when present along with either the carbonate, sulphate or silicate radicals. If the carbonates or sulphates can be reduced, or the calcium and magnesium removed, there is less possibility of scale formation. When calcium and magnesium occur in water containing bicarbonates, they are classed as carbonate hardness and may cause carbonate deposits on the metal surfaces. When calcium and sulphate radicals occur and are allowed to enter the boiler, a hard sulphate scale may form. If sufficient silicate is present, a hard silicate scale may form. To treat this type of water, the calcium and magnesium must be reduced.

Lime Soda Treatment

Most external chemical systems use a lime reagent to convert free carbon dioxide and bicarbonate to the normal carbonate. When lime (CaO) or hydrated lime $Ca(OH_2)$ is added to the water, the bicarbonate is converted to the carbonate with the precipitation of calcium as the carbonate, and magnesium as the hydroxide. The molecular reactions illustrating the conversion of the dissolved salts for this and subsequent treatments are given in Table II.

The residual calcium or magnesium in the treated water depends upon the solubility of calcium carbonate and magnesium hydroxide.

When non-carbonate hardness (sulphates, chlorides, silicates and nitrates) is present, soda ash is added to accomplish its removal.

The residual calcium ion depends upon the solubility of the calcium carbonate and the amount of soda ash present.

Treatment with Barium

Where the sulphate concentration is high and elimination is desirable, a barium reagent is used. This results in a decrease in soluble solids going to the boiler. The barium sulphate formed is practically insoluble.

Use of Alum and Sodium Aluminate

In many instances, especially in cold-process work, so-called coagulants are used, which, by the formation of gelatinous substances or "flocs," hasten the sedimentation of the insoluble products of the reactions. Aluminum sulphate (alum), sodium aluminate and ferrous sulphate (copperas), are used. There is considerable uncertainty as to the exact chemical reactions of alum and sodium aluminate when added to alkaline waters. The work of recent investigators indicates that the reactions involved are not cases of simple hydrolysis, as was formerly thought.[1]

Effect of Temperature Changes

The rate of chemical reactions increases with temperature rise. Consequently, where equipment space is limited, hot processes may be desirable.

Zeolite (Base Exchange) Process

The Zeolite (base exchange) Process practically removes the scale-forming calcium and magnesium and introduces sodium, which is not scale-forming.

Zeolite (a hydrous sodium aluminum silicate whose approximate composition is $2\ SiO_2 \cdot Al_2O_3 \cdot Na_2O \cdot 6\ H_2O$) must be regenerated when the available sodium is exhausted. The zeolite is made available for re-use when a salt brine has passed through the zeolite bed, and the sodium has replaced the calcium and magnesium.

The introduction of sodium products in the boiler may be objectionable due to the gradual concentration of the soluble solids and high alkalinities. When high alkalinities result from such treatment of high carbonate waters, pre-treatment may be desirable. However, such cases require special studies. The relative quantity of dissolved solids resulting from treating the same natural water by lime-barium, lime-soda ash and zeolite increase in the order named.

Internal Chemical Treatment

Higher boiler ratings, higher operating pressures and longer operating periods have resulted in directing greater attention to internal treatment. Basic reactions are involved, a complete understanding of which requires data regarding solubilities at higher temperatures. Not all these data are available.

Soda Ash Treatment

Waters containing a low concentration of calcium and magnesium may be advantageously treated without an external system. Soda ash has been widely used in such cases.

The reactions are reversible. Thus an excess of sulphate may cause calcium sulphate scale to form. The completeness of the reaction depends upon the solubility of the various salts, the amounts present and the temperature. At higher temperatures the carbonate decomposes to form hydroxide, liberating carbon dioxide.

Hydroxide will not prevent the formation of sulphate scale; hence sodium carbonate is not always suitable for scale prevention at higher operating pressures. (No specific upper pressure limit may be stated as plant operating condition, boiler design, local water supply and related factors must be considered.) Hydroxide is effective in converting magnesium to the insoluble magnesium hydroxide, a suspension.

---

[1] Boiler Feed Water Purification, S. T. Powell, 1927, McGraw-Hill, page 29.

Sodium Aluminate Treatment

Sodium aluminate has been applied in some installations for internal treatment. It increases the alkalinity of the water, and forms a "floc," which assists in sedimentation of suspended solids.

Phosphate Treatment

Experience has shown that at operating pressures above 200 lb. per sq. in., with local conditions considered, phosphate treatment is more effective than soda ash for the prevention of scale because of the chemical stability of the calcium and magnesium phosphate. The phosphate compounds formed remain in suspension in the water and will not produce scale, providing the necessary excess of phosphate reagent is present.

Trisodium phosphate is usually used. In event the raw water contains a high bicarbonate content, hydroxide will be generated in the boiler under imposed temperature conditions. If the hydroxide concentration developed in the boiler is excessive, it may be diminished by using disodium phosphate—Na_2HPO_4; monosodium phosphate—NaH_2PO_4; or phosphoric acid—H_3PO_4.

Silicate, if present in sufficient quantity, may form a hydrous magnesium silicate scale. In the presence of hydroxide alkalinity, the silicate usually forms the soluble sodium silicate and silicate scale does not form.

Phosphate is also an inhibitive for embrittlement, a type of boiler metal failure attributed by some to high caustic soda concentration in the boiler. The experimental work of Professor Parr[2] and F. G. Straub of the University of Illinois has shown that the presence of a comparatively small amount of phosphate will inhibit caustic embrittlement.

Sulphuric acid, sodium sulphate, sodium bisulphate, or aluminum sulphate treatment is generally resorted to for the prevention of embrittlement. The presence of sodium sulphate in the boiler in a definite relationship to methyl-orange alkalinity as sodium carbonate inhibits embrittling action. This relationship varies with the boiler pressure and has been recommended in the A.S.M.E. Boiler Code, 1926.[3]

Working Pressure of Boiler, lb. per sq. in. gage	Relation of Sodium Carbonate Alkalinity	to	Sodium Sulphate
0—150	1		1
150—250	1		2
250 and over	1		3

Deconcentration by Boiler Blow-down

At high boiler ratings the presence of soluble and insoluble solids in the boiler water causes trouble due to "carry-over." To control the concentration of these solids, various types of blow-down apparatus are employed. Some involve the use of continuous blow-down with heat exchangers. This method increases the total make-up. Another method uses a small volume of blow-down to control soluble solids and a recirculation of the hot boiler water through equipment which removes the suspended solids, thus controlling the amount of these solids. Still another method involves the use of a small continuous blow-down and a circulation of the hot water through a modified hot-process external treatment system back to the boiler. Here likewise a control of soluble and insoluble solids is maintained. The mixture of zeolite treated water with untreated water in the boiler, coupled with continuous blow-down and recirculation, is still another method. All of these processes use the principle of removing from the boiler a part of the water to control concentration.

TREATMENT CALCULATIONS

The data required for calculating the quantity of chemical reagents for initiating the treatment of water, or to make comparative studies include: (1) The analysis of water; (2) the selection of the reagents required, and a knowledge of the reactions involved between the dissolved elements and the treating reagents.

Statement of Analysis

The ionic form of stating the dissolved substances in water has been adopted in this report, and was necessary because of erroneous deductions which are drawn from hypothetical, or so-called probable combinations. The mineral substances commonly found in water are present predominantly as ions, rather than as compounds. A condition of 98 per cent dissociation may be shown to exist in water containing dissolved mineral substances under 2000 parts per million. It is evident that the arbitrary union of any two ions or radicals to form a compound is empirical, failing to conform to dissociation data. Fundamental data are not available concerning the solubility of a single compound in the presence of other dissolved compounds under boiler operating conditions.

Among proponents of the hypothetical statement there is no agreement. Some develop combinations to state the quality of water as they suppose it exists in the natural state. Some formulate the combinations in an attempt to state the quality as the water would behave when evaporated. The first mentioned group emphasizes the non-scale forming compounds; the latter favors the scale-forming. Another erroneous deduction is made by attempting to calculate to compounds the radicals found by analysis in boiler scale, and so evaluate the water. The actual state of combination of the radicals in boiler scale may only be correctly determined by a petrographic study of the crystals.

---

[2] Embrittlement of Boiler Plate by Samuel W. Parr and Frederick G. Straub, Bulletin No. 177 Engineering Experiment Station, University of Illinois Bulletin, Vol. XXV, No. 4, page 45, June 5, 1928.

[3] Suggested Rules for the Care of Power Boilers, Section VII, A. S. M. E. Boiler Construction Code, 1926, American Society of Mechanical Engineers, par. C A-5, pages 80-81.

The application of hypothetical combinations results in the following difficulties:

a. The analysis is incorrectly used to determine the quality of a water, and to prescribe treatment and processes.
b. The analysis is accepted at its face value by those not familiar with the subject.
c. The analysis cannot be directly compared to other analyses without involved recalculation.

Space prevents a detailed discussion. The interested reader is referred to a complete review of the subject by C. W. Foulk.[4]

The recommended items for the statement of the analysis are shown in Table I.

These data summarize the analytical results in fundamental form. The dissolved substances are stated in ionic form; the interpolated alkalinities and hardness values are shown in the conventional form.

All values are expressed primarily in parts per million (p.p.m.), by weights, except the hydrogen ion concentration, which is expressed as the pH value, and specific conductance expressed as mhos/cm. The use of parts per million simplifies computations, and conformity is established to existing station practice wherein quantity values for water and steam are expressed in pounds.

The milli-equivalent per liter (me) values to which certain parts per million values may be calculated afford a ready visualization of the character of the water. A means is provided to determine the correctness of the analysis.

The milli-equivalent of the ion is the product of the parts per million multiplied by the milli-equivalent factor. The term "milli-equivalent" factor is Stabler's[5] reaction coefficient.

> "The reaction coefficient is measured in more commonly used terms by the ratio of valence to the atomic weight of the radical."

In other words, each ion or radical has a definite combining capacity, and when the weight in parts per million of ions is multiplied by the milli-equivalent factor, the several results are directly comparable. See appendix B for milli-equivalent factors.

Water Treatment Reactions

Calculations for the reagent weights depend upon the reactions and the weight of ions to be treated. The selection of the reagent by the user depends upon the results desired, the process used and costs.

Molecular Reactions

The molecular reactions commonly used are developed in Table II.

Their presentation here differs slightly from previously published form; ionization of the dissolved salt is indicated by the respective electrical charge exponents. The compounds shown without the exponents are either insoluble or undissociated. The only purpose of presenting this deviation in the form of the reactions is to link the reactions with those shown in Table III, Section II, Water Treatment Reactions in Ionic Form.

Ionic Reactions

The ionic reactions are fundamental. Their application to the ions reported in the water analysis is easy. It will be observed that the ion in the water combines with the "active" ion of the reagent, and in some cases, e.g., $BaCO_3$, both ions are "active." To avoid over-treating, such facts must be considered.

Water Treatment Calculations

The calculation factors for water treatment are developed on the basis of ionic analyses and ionic reactions. Factors for seven of the commonly used reagents are presented in Table III, Section III.

Discussion of Table III—Ionic Reactions and Calculation Factors

Section I—Common Reagents for Treatment

The composition of the reagent when in solution is shown in ionic form. Metallic ions (sometimes called bases, positive radicals or cations), possess a positive electrical charge which by convention is shown as a positive exponent ($^+$). The repetition of the exponent is an indication of the combining power (valency) of the ion. Non-metallic ions, (sometimes called acid, negative radicals or anions) possess a negative electrical charge shown by a negative exponent ($^-$).

The data given in Section III are based upon the percentage of composition of the reagents (pure form) and their molecular weights. It must be remembered that after the values in Section III are used, they should be corrected by using the commercial purity values. Complete specifications are given in the Appendix D.

Section II—Water Treatment Reaction in Ionic Form

The ionic reactions developed are fundamental. The application of the reactions is readily made from the ions as reported in the water analysis. The reactions are keyed to the seven commonly used reagents. The user has the choice of reagents, consideration to be given to economic factors and operating conditions.

Section III—Reagent Requirements and Products of Reactions

The development of the numerical data gives for one part per million of the ion in the water to be treated, the weight in parts per million of the selected reagent and the products of reaction.

Application of Molecular and Ionic Reactions

The procedure outlined in the discussion may best be illustrated by applying the reactions to a specific example, as shown in Appendix A.

The water analysis selected at random to show

(a) Variation in composition when reported in hypothetical form
(b) Treatment reactions and calculations

14	$Ca^{++}SO_4^{--}$	+ $Ba^{++}(OH)_2^-$	$\rightleftharpoons Ca^{++}(OH)_2^-$	+ $BaSO_4$	
15	$Ca^{++}Cl_2^-$	+ $Ba^{++}CO_3^{--}$	$\rightleftharpoons CaCO_3$	+ $Ba^{++}Cl_2^-$	
16	$Ca^{++}Cl_2^-$	+ $Ba^{++}(OH)_2^-$	$\rightleftharpoons Ca^{++}(OH)_2^-$	+ $Ba^{++}Cl_2^-$	
	REACTIONS WITH ZEOLITE - Na_2Z *				
17	$Ca^{++}(HCO_3)_2^-$	+ Na_2Z	$\rightleftharpoons 2(Na^+HCO_3^-)$	+ CaZ **	
18	$Mg^{++}(HCO_3)_2^-$	+ Na_2Z	$\rightleftharpoons 2(Na^+HCO_3^-)$	+ MgZ **	
19	$Ca^{++}SO_4^{--}$	+ Na_2Z	$\rightleftharpoons Na_2^+SO_4^{--}$	+ CaZ	
20	$Mg^{++}SO_4^{--}$	+ Na_2Z	$\rightleftharpoons Na_2^+SO_4^{--}$	+ MgZ	
21	$Ca^{++}Cl_2^-$	+ Na_2Z	$\rightleftharpoons 2(Na^+Cl^-)$	+ CaZ	
22	$Mg^{++}Cl_2^-$	+ Na_2Z	$\rightleftharpoons 2(Na^+Cl^-)$	+ MgZ	
	REGENERATION OF ZEOLITE - BACKWASHING WITH SALT - $NaCl$				
23	CaZ	+ $2(Na^+Cl^-)$	$\rightleftharpoons Na_2Z$	+ $Ca^{++}Cl_2^-$	
24	MgZ	+ $2(Na^+Cl^-)$	$\rightleftharpoons Na_2Z$	+ $Mg^{++}Cl_2^-$	

GENERAL NOTES:

The reactions shown should be considered as probably occurring at temperatures below 210°Fahr.

Items shown without positive or negative charges are in molecular form, and are removed from the reaction by precipitation or gaseous evolution, for example, $CaCO_3$ is precipitated, CO_2 is evolved. Items shown with the charges remain in solution in ionic form.

DETAILED NOTES:

Items 1 to 7.

Calcium sulphate, sodium sulphate, calcium chloride, sodium chloride, silica and oxide of iron and alumina do not react with lime.

Items 8 - 9.

Sodium sulphate, sodium chloride, silica and oxide of iron and alumina do not react with soda. The preliminary lime treatment removes the temporary, or bicarbonate (calcium and magnesium bicarbonate) hardness, and some of the permanent hardness ($MgSO_4$+ $MgCl_2$). The ensuing soda treatment removes the remaining permanent hardness ($CaSO_4$ and $CaCl_2$) originally present in the water and the $CaSO_4$ and $CaCl_2$ formed by the lime treatment.

Items 10 - 11.

Where the water originally has only permanent hardness, preliminary lime treatment is unnecessary, and reactions 10 and 11 take place.

Item 12.

On account of the solubility of magnesium carbonate, a sufficient amount of lime should be added to the water to convert the soluble magnesium carbonate to the insoluble magnesium hydroxide as reaction 12.

Items 13 to 16.

Barium compounds after lime treatment are chiefly used for the removal of excessive sulphate. (Soda treatment does not remove sulphate; if calcium sulphate is present soda removes the calcium but leaves the soluble sodium sulphate). The reactions of barium treatment after lime treatment are 13 to 16.

Items 17 to 24.

Sodium salts, silica and oxide of iron and alumina do not react with zeolite.

* Na_2Z, CaZ, and MgZ are not the true chemical formulae of sodium, calcium and magnesium zeolite. Because of their complicated nature the radicals are represented arbitrarily by Z. The approximate formula of zeolite, which is a sodium aluminum silicate, is, $2\ SiO_2.Al_2O_3,Na_2O.6H_2O$.

** Zeolites are exchange silicates, having the power of exchanging the bases which they contain for other bases brought in contact with them. The sodium of the zeolite is replaced by the calcium and magnesium in the water. In the regeneration with salt solution ("backwashing"), sodium is re-introduced and the calcium and magnesium are removed as the soluble chlorides.

ITEM NO.	DISSOLVED SALT	TREATING REAGENT		REACTION PRODUCTS

Items 25 to 30.

Technical trisodium phosphate contains 12 molecules of water of crystallization, but because the water does not enter into the reactions it is not included in the equations.

Sodium bicarbonate, sodium carbonate, sodium sulphate, sodium chloride, silica, and oxide of iron and alumina do not react with trisodium phosphate.

When sodium hydroxide, NaOH, is present in the boiler water in excess (which is frequently the case) the use of disodium phosphate, $Na_2HPO_4 \cdot 12H_2O$ is preferable. These reactions of disodium phosphate are reactions 31 to 36 incl. Monosodium phosphate, $NaH_2PO_4 \cdot 12H_2O$, or phosphoric acid, H_3PO_4, may also be used. The reactions for monosodium phosphate and phosphoric acid are given in reactions 37 to 43 incl., and reactions 44 to 51 incl.

Items 31 to 36.

Technical disodium phosphate usually contains 12 molecules of water of crystallization, but because the water does not enter into the reactions it is not included in the equations.

* Sodium hydroxide is usually present in boiler water.

** In the present of excess hydrate, bicarbonate is converted to carbonate.

Sodium bicarbonate, sodium carbonate, sodium sulphate, sodium chloride, silica and oxide of iron and alumina do not react with disodium phosphate.

Items 37 to 43.

Technical monosodium phosphate usually contains one molecule of water of crystallization, but because the water does not enter into the reactions it is not included in the equations.

* Sodium hydroxide is usually present in boiler water.

** In the presence of excess hydrate, bicarbonate is converted to carbonate.

Sodium sulphate, sodium chloride, silica and oxide of iron and alumina do not react with monosodium phosphate.

Items 44 to 51.

* Usually present in boiler water.

** In the presence of excess hydrate, bicarbonate is converted to carbonate.

Sodium sulphate, sodium chloride, silica, and oxide of iron and alumina do not react with phosphoric acid.

Items 52 to 55.

Calcium sulphate, magnesium sulphate, sodium sulphate, calcium chloride, magnesium chloride, sodium chloride, silica, and oxide of iron and alumina do not react with alum.

* Although not a water softener, alum is used in water treatment to aid coagulation and sedimentation. Alum is also a "neutralizer" and changes the small amount of calcium and magnesium carbonates remaining after lime treatment to calcium sulphate.

** The gelatinous aluminum hydroxide "floc" envelops the finer particles of suspended matter in the water and gathers them into particles of larger size, thus aiding sedimentation. Recent investigation indicates the composition of the alum "floc" in alkaline waters not to be as simple as shown here. Its composition is not definitely known and considered to be highly complex.

Sodium aluminate ($Na_2Al_2O_4$) is also used in conjunction with lime-soda treatment. Like alum, it aids coagulation and sedimentation. There is also considerable uncertainty concerning the reactions involved. With calcium bicarbonate its reaction may be considered as shown below with greater complexity in the aluminum "floc" than is shown. With magnesium bicarbonate its reaction is even more questionable; some investigators have considered that a magnesium aluminate is formed. It appears to have no reaction with calcium sulphate.

$$Ca^{++} + (HCO_3)_2^- + Na_2Al_2O_4 + 4H_2O \rightleftharpoons Al_2(OH)_6^{**} + CaCO_3 + Na_2^+ \; CO_3^{--} + 2H_2O$$

Calcium + bicarbonate + sodium aluminate and water ⇌ aluminum hydroxide ("floc") (precipitated) + calcium + carbonate (precipitated) + sodium + carbonate + water

$$\Updownarrow$$

$$2NaOH + Al_2(OH)_6$$

$$\Updownarrow$$

$$2Na^+ + 2(OH)^-$$

sodium + hydroxide

TABLE

WATER TREATMENT—IONIC

SECTION I—COMMON REAGENT FOR WATER TREATMENT

Chemical Name	Common Name	Formula	Mol.Wt	Metallic Ion		Non-Metallic Ion		Commercial Purity
				Symbol	%	Symbol	%	
Calcium Oxide	Unslaked Lime	CaO	56.1	Ca^{++}	71.47	OH^-	60.65	85% CaO
Calcium Hydroxide	Slaked Lime	$Ca(OH)_2$	74.1	Ca^{++}	54.09	OH^-	45.91	90% $Ca(OH)_2$
Barium Carbonate	Witherite	$BaCO_3$	197.4	Ba^{++}	69.60	CO_3^{--}	30.40	98% $BaCO_3$
Barium Hydroxide	Milk of Barium	$Ba(OH)_2 \cdot 8H_2O$	315.5	Ba^{++}	43.54	OH^-	10.78	50% $Ba(OH)_2$
Sodium Carbonate	Soda Ash	Na_2CO_3	106.0	Na^+	43.39	CO_3^{--}	56.61	98% Na_2CO_3
Sodium Hydroxide	Caustic Soda	$NaOH$	40.0	Na^+	57.48	OH^-	42.52	98% $NaOH$
Tri-Sodium Phosphate		$Na_3PO_4 \cdot 12H_2O$	380.2	Na^+	18.14	PO_4^{---}	24.99	96% $Na_3PO_4 \cdot 12H_2O$
Di-Sodium Phosphate		$Na_2HPO_4 \cdot 12H_2O$	358.2	Na^+	12.84	HPO_4^{--}	26.81	94% $Na_2HPO_4 \cdot 12H_2O$
Sodium Silicate	Water Glass	$Na_2O \cdot SiO_2 \cdot H_2O$			Varies		Varies	
Ferrous Sulfate	Copperas, Sugar of Iron	$FeSO_4 \cdot 7H_2O$	278.0	Fe^{++}	20.09	SO_4^{--}	34.55	98% $FeSO_4 \cdot 7H_2O$
Aluminium Sulfate	Alum	$Al_2(SO_4)_3 \cdot 18H_2O$	666.4	Al^{+++}	8.09	SO_4^{--}	43.39	111% $Al_2(SO_4)_3 \cdot 18H_2O$

Reactions assume temperature below 210°F.
Application. To compute from ionic analysis reagents weights for initiating treatment:
Select desired reactions from Section II. By Key to Section III note soluble products.
Select reaction to treat soluble product (except Na+).
Multiply reagent factor (Section III) by parts per million of ion treated. Total each reagent.
Reaction products similarly calculated.
Weight of Commercial Reagent = Weight of Pure Reagent × 100 ÷ Commercial Purity %.

SECTION III—REAGENT REQUIREMENTS AND PRODUCTS OF REACTION

was selected from Bulletin 29 (ibid reference 4) p. 340. The water is from Lake Erie, sampled at Painesville, Ohio; the composition reported in ionic form was:

	p.p.m.
Total solids	196
Total hardness as $CaCO_3$	117
Carbonate hardness as $CaCO_3$	100
Non-carbonate hardness as $CaCO_3$	17
Magnesium	9.7
Calcium	35
Sodium and potassium	10
Iron, ferrous	1.2
Bicarbonate	122
Chloride	14
Nitrate	0.25
Sulphate	15
Silica	12
Free carbon dioxide	2

This analysis is calculated to hypothetical form—See Table IV—using seven widely published procedures, and one procedure privately communicated. In spite of the fact that free carbon dioxide is reported, all the methods except No. 5 show the presence of normal carbonates instead of bicarbonate. To the engineer, the variations are sufficiently divergent to lead him to believe that the analyses represent more than one water supply.

The numerical factors for the molecular reactions (Table II) have not been calculated. These may be derived by stoichiometric methods. The interested reader is referred to the references appended to Table IV and, in addition, to Bulletin 29, Geological Survey of Ohio, Industrial Water Supplies, Foulk, 1925, Chapter XI, pp. 123 to 159, and to Boiler Feed Water Purification, S. T. Powell, Table XVIII, p. 332.

INDIVIDUAL STATEMENT

The following statement of routine plant control for boiler water conditioning using a lime and soda ash process is contributed by Mr. O. K. Smith, United Light and Power Engineering and Construction Co.

The growing tendency during the past few years toward higher pressures and higher ratings has called for more exacting methods of feed water control. It is obvious that the higher the pressure, and especially the rating carried, the greater will be the tendency toward scale formation. This demands a minimum amount of incrustating solids going to the boilers from whatever treating system is in use, and the blow-downs or deconcentrating equipment carefully regulated.

In using the Lime and Soda Process, it is necessary to give the operation very close attention and to accurately control the reactions in order to reduce to a minimum the total amount of dissolved solids in the water leaving the treating apparatus. At best, there will be left in the water between 17 and 34 parts per million (1 to 2 grains per gallon) of hardness as calcium carbonate, due to the slight solubilities of calcium carbonate and magnesium hydroxide. Water treating apparatus manufacturers[6] have published diagrams designed to give the operator a rapid method of determining the condition of the treated water and an approximate degree of rectitude in the rate of chemical feed. A chart has been designed to permit reducing the total solids in the treated water to a minimum by close control of the excess chemical feed.

---

[6] Examples of such charts are published in "Finding and Stopping Waste in Modern Boiler Rooms," Cochrane Corp., 1928, page 735 and 737.

The chart depends upon the relation of carbonate, bicarbonate and hydroxide alkalinity as parts per million of calcium carbonate and the interpolated reagent weights. The tests for the alkalinities are made by neutralizing a 100 c.c. sample of water with N/20 sulfuric acid to both the phenolphthalein (Pht) and methyl-orange (M.O.) end points.

The rate of increase or decrease of lime and soda ash in pounds per 1,000,000 lb. water treated is read directly from the chart so that the alkalinities of the water can be maintained at all times within the area marked "Degree of Tolerance." The Degree of Tolerance has been designed to give approximately 17 parts per million of normal carbonate alkalinity above the solubility of the incrusting carbonates in the water. The area is also located slightly in the zone of hydroxide alkalinity with respect to the addition of lime, or reduction in carbonate hardness. The magnesium should be quite completely removed as the hydroxide, leaving the principal incrusting carbonate as the calcium salt which has a solubility of approximately 20 parts per million. It is understood, of course, that with the addition of soda ash to raw water, the incrusting sulphates are first acted upon, giving partially soluble magnesium carbonate and calcium carbonate as a precipitate. The magnesium being further acted upon by excess lime producing the more insoluble magnesium hydroxide and calcium carbonate, it is readily seen that with a normal carbonate greater than the solubility of calcium carbonate as shown by titration, the complete reduction of non-carbonate hardness is indicated. This is believed to be a more accurate method of controlling the hardness, and practically eliminates the soap test, except possibly as a check, in cases where the normal carbonate test is below the solubility as stated above or in cold processes where reactions are not so complete.

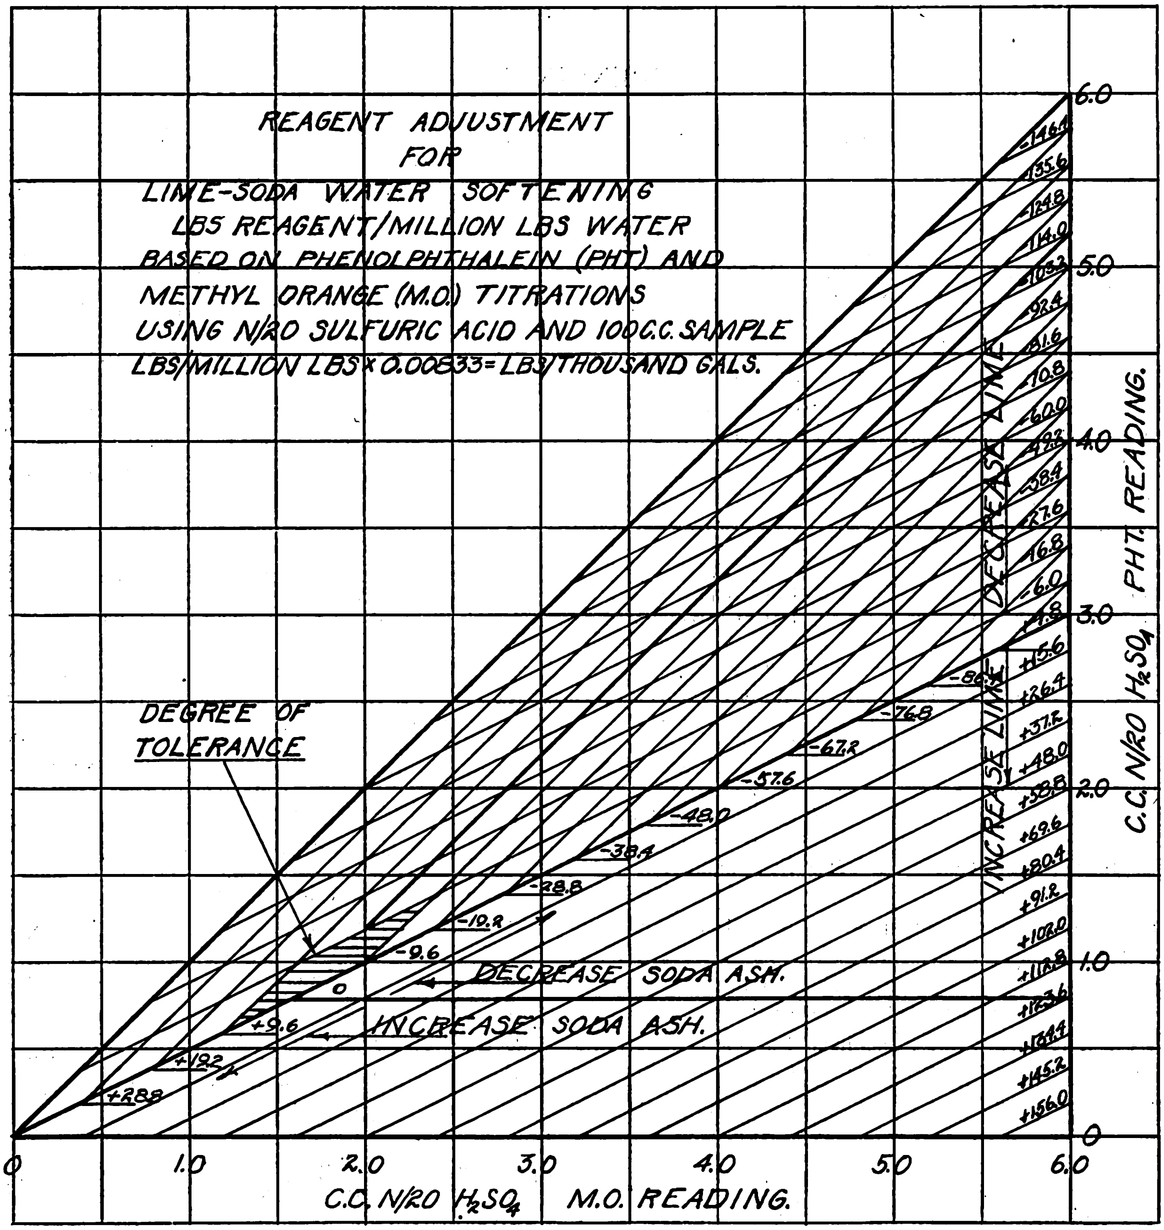

FIG. 1—REAGENT ADJUSTMENT FOR LIME-SODA SOFTENING SYSTEM.

It is necessary to carry a slight alkalinity in order to overcome corrosion and scale formation from small amounts of suspended matter. This point should be kept as low as possible due to the possibility of setting up caustic embrittlement under certain conditions. The chart gives a close approximation of the rate of increase or decrease of chemical feed assuming 70 per cent available calcium hydroxide. For the sake of clarity, the quantitative determination of the bicarbonate, carbonate and hydroxide alkalinity as calcium carbonate are shown in another chart under the section Methods of Testing (see Fig. 4.)

The use of the chart is best understood by applying the following examples:

Example 1. Treated water containing bicarbonate and carbonate alkalinity as $CaCO_3$

Readings obtained on testing 100 c.c. of water gave:
Pht. reading 1.0 c.c. N/20 H_2SO_4
M.O. reading 2.8 c.c. N/20 H_2SO_4

By reference to Fig. 1, the coordinates 1.0 and 2.8 intersect on a 34 deg. diagonal. Follow this diagonal to the right and note an increase of 26.4 lb. of lime is required. From the intercept read horizontally to the left to the heavy 34 deg. diagonal, and note a decrease of 9.6 lb. of soda ash per 1,000,000 lb. of water is required. The adjustments will produce a treated water the quality of which falls within the "degree of tolerance" area.

Example 2. Treated water containing carbonate and hydroxide alkalinity as $CaCO_3$

Readings obtained on testing 100 c.c. of water gave:
Pht. 1.6 c.c. N/20 H_2SO_4
M.O. 2.4 c.c. N/20 H_2SO_4

The coordinates 1.6 and 2.4 intersect on a 34 deg. diagonal. Follow this diagonal to the right and note a decrease of 16.8 lb. of lime per 1,000,000 lb. of water is required. The coordinates also intersect on a 45 deg. diagonal. Follow this diagonal to the left, and note zero change in soda ash is required. The adjustments indicated will produce a treated water, the quality of which falls within the "degree of tolerance" area.

APPENDIX A

CALCULATIONS FOR CONDITIONING REAGENTS BASED ON IONIC ANALYSIS OF WATER

Water analysis in ionic form, parts per million

Carbon dioxide	CO_2	2	Bicarbonate	HCO_3	122
Calcium	Ca	35	Sulphate	SO_4	15
Magnesium	Mg	9.7	Chloride	Cl	14
Sodium	Na	10	Nitrate	NO_3	0.25

The reactions applied and factors used are for:

CO_2 —Reaction h, Section II; Section III, 6-C
Mg —Reaction u, Section II; Section III, 14-C
HCO_3 —Reaction d, Section II; Section III, 3-C
Ca —Reaction e, Section II; Section III, 4-E

Lime CaO requirements, products formed, and soluble ions introduced.

Item*			
1.	$2 CO_2 \times 1.28$ CaO	=	2.6 CaO required
1a.	$2 CO_2 \times 2.27\ CaCO_3$	=	4.5 $CaCO_3$ precipitated product
2.	9.7 Mg $\times$ 2.31 CaO	=	22.4 CaO required
2a.	9.7 Mg $\times$ 2.40 $Mg(OH)_2$	=	23.3 $Mg(OH)_2$ precipitated product
2b.	9.7 Mg $\times$ 1.65 Ca	=	16.0 Ca soluble ion introduced
3.	122 $HCO_3 \times 0.46$ CaO	=	56.1 CaO required
3a.	122 $HCO_3 \times 0.82\ CaCO_3$	=	100.0 $CaCO_3$ precipitated product
3b.	122 $HCO_3 \times 0.49\ CO_3$	=	59.8 CO_3 soluble ion introduced

Soda ash Na_2CO_3 requirements, products formed and soluble ions introduced.

Ca to be conditioned includes 35 p.p.m. in original water plus 16 p.p.m. introduced in item 2b = 51. p.p.m. Ca

4.	51 Ca $\times$ 2.64 Na_2CO_3	=	134.5 Na_2CO_3 required
4a.	51 Ca $\times$ 2.50 $CaCO_3$	=	127.5 $CaCO_3$ precipitated product
4b.	51 Ca $\times$ 1.15 Na	=	59.7 Na soluble ion introduced

Note: It will be noted that in item 3b 59.8 p.p.m. Co_3 ion was introduced, and this amount when calculated to the soda ash equivalent $\frac{106\ Na_2CO_3}{60\ CO_3} = 1.767$ will reduce the amount of Na_2CO_3 required for the conditioning of the Ca ion.

4c.	59.8 $Co_3 \times 1.767$	=	105.7 Na_2CO_3
4d.	134.5 Na_2CO_3 — 105.7 Na_2CO_3	=	28.8 Na_2CO_3 actually required
4e.	58.7 Na — 46.2 Na	=	12.5 Na soluble ion actually introduced

Summarizing

Lime required, pure chemicals = 81.1 p.p.m.
Item 1 + 2 + 3
Soda ash required, pure chemicals = 28.8 p.p.m.
Item 4d

Lime required, commercial chemicals $= 81.1 \times \frac{100}{85} =$ 95.4 lb. per 1,000,000 lb. water

Soda ash required, commercial chemicals $= 28.8 \times \frac{100}{98} =$ 29.4 lb. per 1,000,000 lb. water

Soluble ions found in the conditioned water:

				p.p.m.
Na	— 10	raw water + 12.5 (Item 4e)	=	22.5
SO_4	— 15	raw water	=	15
Cl	— 14	raw water	=	14
NO_3	— 0.25	raw water	=	0.25

Non-soluble precipitated products formed removable by sedimentation and filtration

			p.p.m.
$CaCO_3$	— Items (1a) + (3a) + (4a) 4.5 + 100 + 127.5	=	232.0
$Mg(OH)_2$	— Item (2a)	=	23.3

NOTE: No corrections have been applied in the summary for the solubility of $CaCO_3$ and $Mg(OH)_2$, nor has allowance been made for the arbitrary excess of CaO and Na_2CO_3 weights usually added.

---

* The item numbers refer to sequence in calculations, and not to the designation in the table.

APPENDIX B

TABLE V

CONVERSION FACTORS PARTS PER MILLION TO MILLI-EQUIVALENTS

Name of Ion	Molecular or Atomic Weight	Combining Value	Milli-Equivalent Factor Multiply by
Aluminum	26.97	3	0.1107
Barium	137.37	2	0.0146
Bicarbonate	61.008	1	0.0164
Calcium	40.07	2	0.0499
Carbonate	60.0	2	0.0333
Chloride	35.457	1	0.0282
Hydrogen	1.008	1	0.9921
Hydroxide	17.008	1	0.0588
Iron, ferric	55.84	3	0.0537
Iron, ferrous	55.84	2	0.0358
Magnesium	24.32	2	0.0822
Nitrate	62.008	1	0.0161
Phosphate	95.027	3	0.0316
Sodium	22.997	1	0.0435
Sulphate	96.064	2	0.0208

$$\text{Milli Equivalents} = \text{p.p.m. of ion} \times \frac{\text{Combining Value}}{\text{Mol. or At. Wt.}}$$

The formula for determining the correctness of the analysis is:

$$\text{Error} = 100\,\frac{\text{pe} - \text{ne}}{\text{pe} + \text{ne}}$$

pe = sum of metallic ion equivalents
ne = sum of non-metallic ion equivalents

Error need not exceed 5 per cent values for waters containing 100 or more parts per million.

Miscellaneous Factors

Dissolved Oxygen

p.p.m. by weight × 0.6975 = c.c. per liter
c.c. per liter × 1.4337 = p.p.m. by weight

Alkalinities and hardness in terms of calcium carbonate

Bicarbonate ion (HCO_3) p.p.m. × 0.8197 = (HCO_3) alkalinity as $CaCO_3$ p.p.m.

Carbonate ion (CO_3) p.p.m. × 1.667 = CO_3 alkalinity as $CaCO_3$ p.p.m.

Hydroxide ion (OH) p.p.m. × 2.941 = (OH) alkalinity as $CaCO_3$ p.p.m.

Calcium ion (Ca) p.p.m. × 2.497 = (Ca) hardness as $CaCO_3$ p.p.m.

Magnesium ion (Mg) p.p.m. × 4.115 = (Mg) hardness as $CaCO_3$ p.p.m.

Sulphate — alkalinity ratio

Total alkalinity as $CaCO_3$ × 1.06 = alkalinity as sodium carbonate p.p.m.

Sulphate ion (SO_4) × 1.479 = sodium sulphate, p.p.m.

APPENDIX C

CONDUCTANCE CALCULATIONS FROM IONIC ANALYSIS

The primary purpose of this calculation is to show the high degree of ionization of the soluble salts in water. It can also be used to check the accuracy of the analytical procedure.

The specific conductance of a water was measured before analysis and gave a value of 49.6×10^{-4} mhos per cm. at 25 deg. cent. The dissolved solids determined by evaporation was 2,150 p.p.m. After the analysis was completed, the specific conductance of the water was calculated using the equivalent ionic conductance of the various ions.

TABLE VI

Ions by Analysis	Milli-equivalents per million	Equivalent Ionic Conductance mhos per equiv. at 25 deg. cent.	Specific Conductance mhos per cm. × 10^6 at 25 deg. cent.
Hydrogen	—	× (a) 350.	= —
Calcium	1.297	× (a) 60.	= 77.82
Magnesium	0.066	× (b) 53.7	= 3.54
Sodium	33.637	× (a) 50.9	= 1712.12
Carbonate	1.322	× (c) 69.	= 91.22

APPENDIX D

SPECIFICATIONS FOR REAGENTS USED IN WATER TREATMENT

Lime (CaO)

Slaking

When lumps of quicklime are immersed in water, they shall readily disintegrate into a suspension of finely divided material.

Chemical Requirements

1—For quicklime the standard of composition shall be a content of 85 per cent available calcium oxide (CaO), but quicklime of less CaO content may be accepted where conditions of service permit and the price of the less pure product is such as to give increased economy considering the additional quantity of both lime and sludge to be handled.

2—For hydrated lime the standard shall be a content of 90 per cent available calcium hydroxide ($Ca(OH)_2$). The magnesium salt content shall be less than 3 per cent.

Bonus and Reduction

Where large quantities of lime are to be purchased it is recommended that the contract be drawn to include a bonus or a reduction of 1.5 per cent in payment for each 1 per cent by which the available CaO or $Ca(OH)_2$ exceeds or falls below the standard percentage. In case of small purchases the contract should permit rejection for failure to reach the standard.

Packing and Shipment

Quicklime may be shipped in bulk, in wooden barrels, in metal drums or in waterproof bags, packages of each kind to be of uniform weight. Hydrated lime is usually shipped in paper bags holding 50 lb. net each.

Soda Ash (Na_2CO_3)

Chemical Requirements

The soda ash shall be that known as 58 per cent light soda ash and shall contain not less than 98 per cent of sodium carbonate (Na_2CO_3). The material shall be in a dry powdered form, shall contain no large lumps or large crystals, and shall be free from chips and other foreign matter.

Caustic Soda (NaOH)

Chemical Requirements

The caustic soda shall be that known as 76 per cent actual test sodium oxide and shall contain not less than 98 per cent sodium hydroxide (NaOH). The dry material is manufactured in three forms, viz. solid, ground and flaked.

Packing and Shipment

Solid caustic soda is customarily shipped in steel drums containing approximately 700 lb. net weight. The ground and flake material is commonly shipped in steel drums or in wooden barrels containing approximately 400 lb.

Barium Carbonate, (Witherite), ($BaCO_3$)

Chemical Requirements

This material shall consist of not less than 98 per cent barium carbonate ($BaCO_3$). The hydrochloric acid insoluble matter shall be less than ½ of 1 per cent.

Packing and Shipment

Barium carbonate may be shipped in bulk, in bags of uniform weight or in barrels of uniform weight.

Barium Hydroxide, ($Ba(OH)_2.8H_2O$)

Chemical Requirements

This substance shall contain at least 50 per cent of barium hydroxide, $Ba(OH)_2$ (anhydrous), shall be readily soluble in warm water and shall contain not more than a trace of iron. Other solid substances should be absent.

Packing and Shipment

Barium hydroxide may be shipped in bulk, in air-tight barrels or kegs of uniform weight.

Trisodium Phosphate, ($Na_3PO_4.12H_2O$)

Chemical Requirements

Trisodium phosphate for water treatment shall contain not less than 24 per cent of available water-soluble PO_4. The water-insoluble matter shall not exceed ½ or 1 per cent.

Packing and Shipment

Trisodium phosphate may be shipped in bulk, in bags of uniform weight or in barrels of uniform weight.

Disodium Phosphate, $Na_2HPO_4 12H_2O$

Chemical Requirements

Disodium phosphate for water treatment shall contain not less than 25 per cent of available water-soluble PO_4. The water-insoluble matter shall not exceed ½ of 1 per cent.

Packing and Shipment

Disodium phosphate may be shipped in bulk, in bags of uniform weight or in barrels of uniform weight.

Sulphate of Alumina ($Al_2(SO_4)_3$ + *Water of Crystallization*)

Chemical Requirements

1. The material shall be basic, shall contain not less than 17 per cent available water-soluble alumina (Al_2O_3) and shall not contain more than 0.75 per cent iron (Fe_2O_3).

Insoluble Matter

1. Sulphate of alumina from which the insoluble material has been removed shall contain not more than 0.5 per cent of material insoluble in distilled water.

2. Sulphate of alumina from which the insoluble material has not been removed shall contain not more than 7.5 per cent of material insoluble in distilled water.

Sizes of Lumps or Grains

1. Lump sulphate of alumina shall range in size from ¾ to 3 in.

2. Ground sulphate of alumina for use in dry-feeding machines shall be of such size that not less than 95 per cent shall pass a woven sieve having 10 meshes per linear in., and 100 per cent shall pass a sieve having 4 meshes per linear in.

Packing and Shipment

1. Sulphate of alumina may be shipped in bulk, in bags of uniform weight or in barrels of uniform weight.

Sulphate of Iron ($FeSO_4.7H_2O$)

Chemical Requirements

1. Sulphate of iron shall be what is commonly known as sugar sulphate of iron theoretical formula, Fe $So_4.7H_2O$.

2. It shall contain not less than 98 per cent of pure ferrous sulphate ($FeSO_4.7H_2O$), not more than 1/15th of 1 per cent of free acid and shall be clean and free from all dirt and particles of foreign matter.

Packing and Shipment

Sulphate of iron may be shipped in bulk in paper-lined, tight box cars, in bags, in barrels or in castors, packages of each kind to be of uniform weight.

Sampling and Testing

1. The composition of the chemicals shall be determined by analyzing samples taken promptly upon the arrival of the material at the point of consumption.

2. When chemicals are shipped in bulk, the sample shall be so taken that it will represent an average of all parts of the shipment from top to bottom, and shall not contain a disproportionate share of the top and bottom layers. It shall weigh at least 10 lb. (in the case of lump lime 100 lb.), and shall be crushed if necessary, mixed thoroughly and "quartered" to provide two 1-lb. samples, one of which shall be kept carefully sealed for use in a possible retest as provided hereinafter.

3. When shipped in packages at least 3 per cent of the number of packages shall be sampled. They shall be taken from various parts of the shipment, dumped, mixed and sampled as in the above paragraph.

4. When sampling quicklime or hydrated lime it is essential that the operation be conducted as expeditiously as possible, in order to avoid undue exposure of the material to the air. The sample to be sent to the laboratory shall immediately be placed in an air-tight container in which the unused portion shall be stored until the shipment has been finally accepted or rejected by the purchaser.

Resampling

1. Notice of dissatisfaction with a shipment based on these specifications must be in the hands of the consignor within 10 days after the receipt of the shipment at the point of destination. If the consignor desires a retest, he shall notify the consignee within 5 days of receipt of the notice of complaint. The duplicate sample shall then be forwarded for a test to some laboratory agreed upon by both parties. This retest shall be made at the expense of the consignor. The results of the retest shall be accepted as final.

LUBRICATION

Committee Statement

Approved test methods for judging the quality of turbine oil are presented under "Recommended Practices" (p. 19) as part of the Committee's activities. Attention is called to the fact that these tests alone are not suitable for determining the comparative desirability of different brands of new oil for turbine lubricating service. They will, however, serve to establish variations in shipments of the same brand of oil and also (especially the Water and Sediment Test, the Steam Emulsion Test, and the Neutralization Number), serve to measure the degree of alteration the oil undergoes in service.

To establish the comparative suitability of various brands of oil an oxidation test of some degree of acceleration should be used. No such test has been included in this group because it has never been approved. Two such tests have received considerable study by some members of the Committee: (1) The Funk Sludge Test and (2) The Rogers Stability Test.

The Committee should consider these two tests with a view to establishing their suitability in selecting oils for turbine service.

Individual Statement

A laboratory study on the sludging of turbine oils has been made by Mr. C. P. Menges, New York Edison Co. This supplements the subcommittee report published in Power Station Chemistry, N. E. L. A. Publication No. 289-28. Mr. Menges reports:

A comparison is made between the data obtained by sludging a sample of turbine oil in a Funk Sludging Machine, and the data obtained by observing the behavior of this oil in a 35,000-kw. G. E. Turbine.

Comparisons are made of the data obtained by sludging heavy and light turbine oils in a Funk Sludging Machine.

From the tests (heavy and light turbine oils) it would not be advisable to draw general conclusions, but it appears that a heavier oil is limited in service to viscosity, while, on the other hand, a lighter oil develops a considerably greater neutralization number and sludge content long before the limiting viscosity is reached. The origin and method of refining of lubricating oils are also important factors.

Data on Oil In Service and Sludged In a Funk Sludging Machine

The oil in No. 12 turbine (35,000 kw.), having an oil reservoir of 1100 gal. capacity, has been in operating service 3757 hr. It had been intended not to add any new oil during the time of test, but owing to work done on the machine, 79 gal. were added to make up for deficiency, after 2726 hr. operation.

Data obtained from the service test and sludging test are presented in tabular form.

At the end of the sludging test, the condition of the oil (assuming an accelerated oxidation of 100:1) was such as would be given by 12,000 hr. of actual service operation. However, after 3757 hr., no sludge developed in the oil, but some sludge and water which did not go into circulation was found in the bottom of the oil reservoir. The probable

TABLE VII

DATA ON TURBINE OIL IN SERVICE

Hr. in Service	Neutralization Number MgKOH	Saybolt Viscosity at 100° F. Seconds	Saponification No. %
110	0.073	240	trace
301	0.098	...	....

* 79 gal. new oil added after 2726 hr. service.

OIL SLUDGED IN FUNK'S SLUDGING MACHINE

After sludging 120 hr.......	0.800	260	2.30

reason for no sludge formation was the absence of any appreciable quantity of water and also the more resistant nature of this oil to oxidation or deterioration as shown in the comparison of light and heavy turbine oil study. It was thought advisable to discontinue the plant test, not so much on account of greater increase in acidity or oxidation, but to prevent the oil from attaining a greater viscosity than 255 sec. at 100 deg. fahr. (Saybolt), which is the limiting viscosity of our system oil. By periodic addition of fresh oil to the system of approximately 25,000 gal., no troublesome sludge was produced. This oil has been in continual service for over 15 yr. De Laval separators are being used to separate the water and the small amount of sludge.

The system oil to date shows the following tests:

Neutralization Number, mg KOH per gm oil.......	0.50
Saponification Number, expressed in per cent.......	1.2
Water, per cent....................................	0.8
Sludge, milligrams per 100 c.c......................	10.4
Saybolt viscosity at 100 deg. fahr., sec.............	255

Previous to the use of this oil, an oil of lower viscosity had been in service. After a short time formation of sludge was noticed in the circulating oil, which gradually separated in the pipe lines and clogged the strainers. This oil was subsequently replaced by the oil now in use, which is giving very satisfactory service.

Comparison of Heavy and Light Turbine Oils in Funk Sludging Machine

Comparative data on three turbine oils are shown graphically in Fig. 2.

The samples were tested in the Funk Sludging Machine under similar conditions. Eight and one-half gal. of oil were circulated at a temperature of 200 deg. fahr., passing a 50 per cent mixture of air and oxygen through the oil at a rate of 10 cu. ft. per hr. No additions of new oil were made during the test. A 100 c.c. sample was withdrawn from the machine each 2 hr. The condensate varied from 200 c.c. to 375 c.c. water each 2 hr. This was not returned to the machine but an equivalent quantity of fresh water was added, the condensate samples being reserved for acid tests, etc.

A marked difference was found in these oils. Neutralization number, sludge and emulsion developed in the lighter oils to a much greatest extent. Sample No. 3 emulsified so badly after 90 hr. that it was difficult to continue the test after that time.

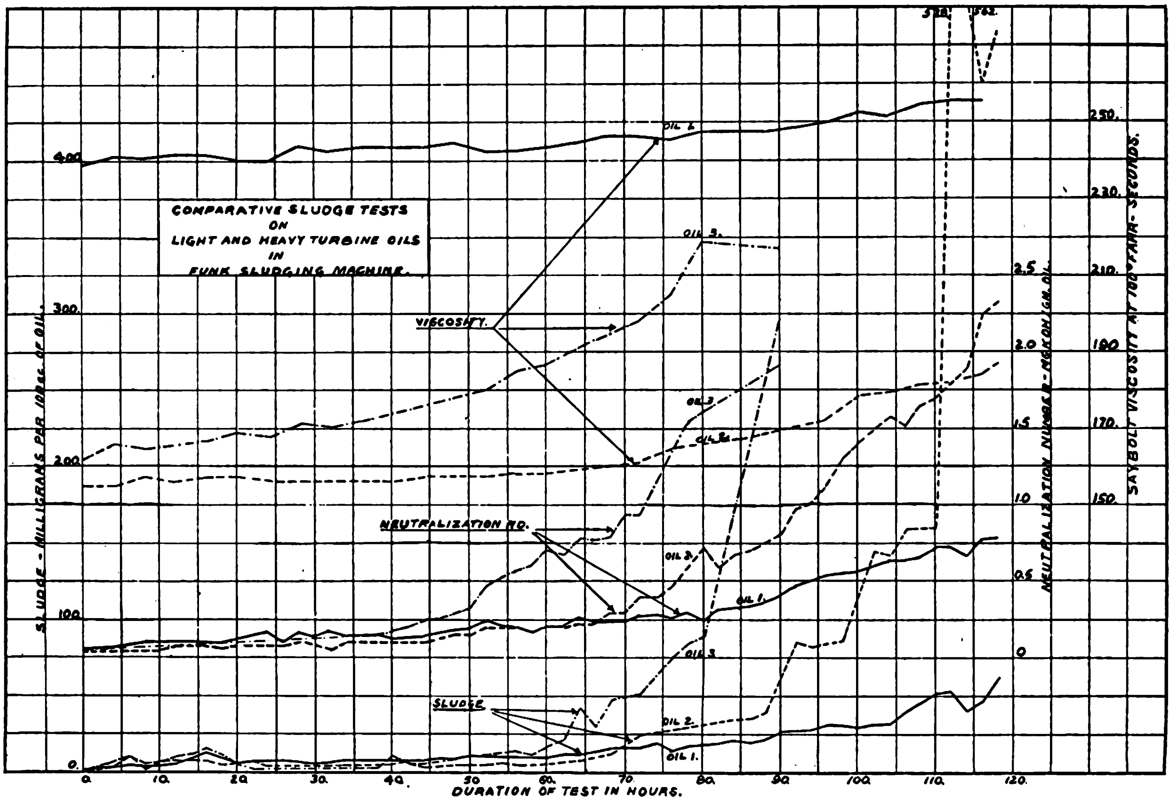

FIG. 2—COMPARATIVE SLUDGE TESTS ON LIGHT AND HEAVY TURBINE OILS IN FUNK SLUDGING MACHINE.

METHODS OF TESTING

Committee Statement

The Committee is assembling recommended test procedures for use in the laboratory and in the field. At a suitable time, the methods will be published in manual form.

Methods of tests for turbine oils have been compiled from various sources. The tests, when applied to new oils to establish variations in quality of various shipments are: Gravity, Flash and Fire, Pour, Viscosity, Steam Emulsion Neutralization Number, Corrosion, Water and Sediment, and Oxidation at High Temperature (Slight Method). Tests, when applied to turbine oils in service to show alteration in quality are: Viscosity, Steam Emulsion, Neutralization Number, Water and Sediment.

The Committee recommends the determination of the hydrogen ion concentration, pH, in the station water supplies. The test is made by either colorimetric or electrometric procedures. Ample operating instructions are furnished by the equipment manufacturers. Powell[7] states:

> The hydrogen ion concentration of a water is a measure of its alkalinity or acidity. This test differs from the ordinary alkalinity or acidity tests because it is not only more delicate, but is indicative of conditions that are not shown by these tests. The test is important in routine practice and is sufficiently simple to be made by plant operators who have no special training in chemistry.
>
> This determination has a specific sphere of usefulness in the control of boiler feed water, since it indicates the active acidity or alkalinity of a water which is not discernible by ordinary titrimetric analyses.
>
> The electrolytic determination of the H-ion concentration consists of measuring a potential difference or electromotive force between two electrodes which form the extremities of a so-called gas chain.
>
> To determine the hydrogen ion concentration by the colorimetric method, 10 c.c. of water to be tested are placed in a test tube and ½ c.c. of a prepared dye (indicator) is added. The treated sample is allowed to stand for 5 min., and the color produced is also allowed to stand for 5 min. and then matched against one of the color standards which have been prepared by the same indicator as used in the test. The number of the standard color tube that matches the treated sample of water is the hydrogen-ion concentration number. The standards are numbered from 0 to 14.0. The tubes above 7.0 may be considered within the alkaline range, and those below 7.0 within the acid range.
>
> The foregoing test is less accurate than the electrometric method. The latter method is also desirable in many instances, since a permanent record may be obtained by the use of recording devices.

The change of the pH in water with rising temperature is shown graphically in Fig. 3. This curve was prepared by Mr. C. H. Fellows, Detroit Edison Co.

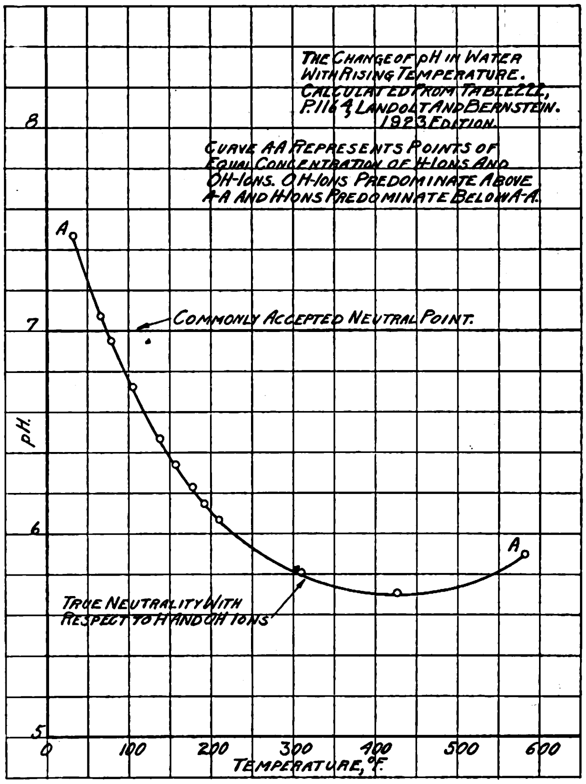

FIG. 3—THE CHANGE OF pH IN WATER WITH RISING TEMPERATURE.

PLANT METHOD FOR THE READY ESTIMATION OF THE VARIOUS ALKALINITIES IN WATER

Individual Statement

Mr. O. K. Smith, United Light & Power Engineering & Construction Co., Davenport, Iowa, presents the following plant method for the ready estimation of the various alkalinities in raw, treated and boiler water.

Method of Test

Measure 100 cc. of the water to be tested in a volumetric flask, and empty into a 200 cc. casserole. Add four or five drops of phenolphthalein (Pht) indicator and titrate the sample with N/20 sulphuric acid until the pink color just disappears.

The number of cc. used is the Pht. reading. Next add two or three drops of methyl-orange (M.O.) indicator to the same sample and continue the titration until the color changes from yellow to orange. The first definite tinge of orange which does not fade on stirring is the end point. The total number of cc. of acid used starting from the beginning of the Pht. titration to the end of the methyl-orange titration is the M.O. reading.

The various alkalinities may be read directly from a chart, eliminating calculations.

The chart is divided into two areas by three datum lines: the x-axis along which the carbonate alkalinity is zero, a heavy 34 deg. diagonal along which bicarbonate and hydroxide alkalinities are zero, and a heavy 45 deg. diagonal along which carbonate alkalinity is zero. (All alkalinities are expressed in parts per million of calcium carbonate).

The area included between the x-axis and the heavy 34 deg. diagonal denotes amounts of carbonate and bicarbonate alkalinity, carbonate alkalinity being indicated by lines parallel to the x-axis, and the bicarbonate alkalinity being indicated by lines parallel to the 34 deg. diagonal.

The area included between the heavy 34 deg. diagonal and the heavy 45 deg. diagonal denotes various amounts of carbonate and hydroxide alkalinities, carbonate alkalinity being indicated by lines parallel to the heavy 45 deg. diagonal, and hydroxide alkalinity being indicated by lines parallel to the heavy 34 deg. diagonal.

Use of Chart

The readings obtained on a sample of water were:

$$a \begin{cases} \text{Pht reading } 1.0 \text{ cc. N/20 } H_2SO_4 \\ \text{M.O reading } 2.8 \text{ cc. N/20 } H_2SO_4 \end{cases}$$

and on another water

$$b \begin{cases} \text{Pht reading } 1.6 \text{ cc. N/20 } H_2SO_4 \\ \text{M.O reading } 2.4 \text{ cc. N/20 } H_2SO_4 \end{cases}$$

By reference to Fig. 2 using the results of test a: the coordinates 1.0 and 2.8 intersect in the area of bicarbonate and carbonate alkalinities, on the horizontal line (read right) showing 50 p.p.m. carbonate alkalinity and on a 34 deg. diagonal, (read obliquely left) showing 20 p.p.m. bicarbonate alkalinity. Using the results of test b: the coordinates 1.6 and 2.4 intersect in the area of carbonate and hydroxide alkalinity; on a 34 deg. diagonal (read obliquely left) showing 20 p.p.m. hydroxide alkalinity, and on a 45 deg. diagonal (read obliquely right) showing 40 p.p.m. carbonate alkalinity.

---

[7] Note—Part of Powell's discussion is presented in Boiler Feed Water Purification by S. T. Powell, McGraw-Hill Book Co., 1927, page 314.

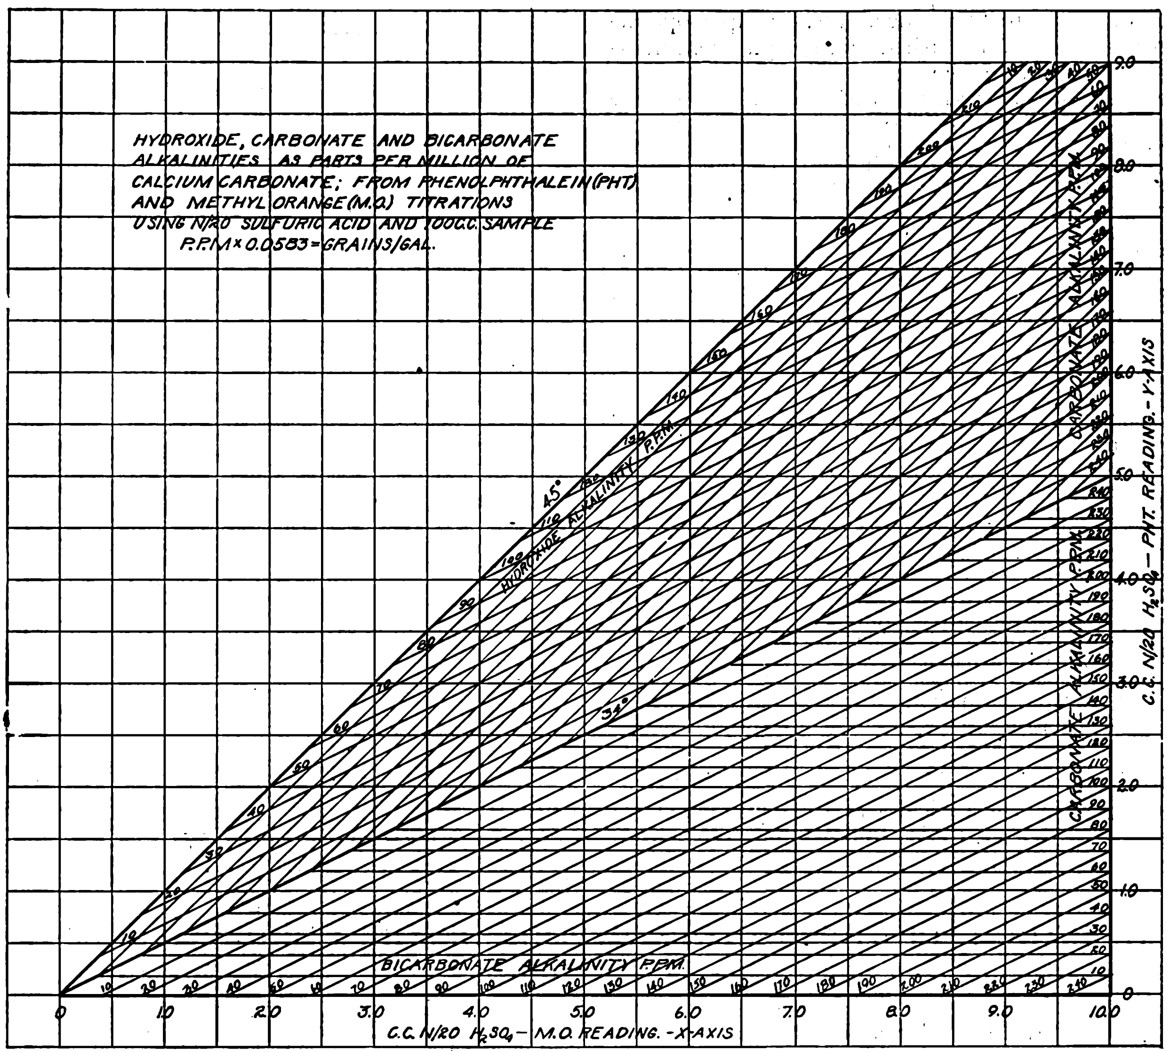

FIG. 4—Ready Estimation of Alkalinities from Titration Values.

TENTATIVE METHODS FOR DETERMINATION OF PHOSPHATE IN BOILER WATER

Scope

In boiler water treatment it is often advisable to use phosphate for treating the water. In order to control the use of phosphate, it is also advisable to be able to determine rapidly and with a fair degree of accuracy, the soluble phosphate in the boiler water at frequent intervals.

Application of Test

The application of this method is intended for use on boiler water samples. If organic matter is present in sufficient amounts to cause a marked coloration of the water, this method cannot be used.

Description of Method of Testing for Phosphate

The test is dependent upon the fact that molybdenum present as phospholybdic acid may be reduced in the presence of an excess of molybdic acid. The reducing agent used is Hydroquinone. If hydroquinone is added to an acid solution of molybdic acid, no phosphate being present, the solution will be colorless when treated with alkaline sulphite; but if phosphate is present, phospholybdic acid is formed and reduced giving a blue color. As small an amount as 5 p.p.m. of phosphate gives a distinct blue color in this test.

Apparatus

1. Glass funnels and filter paper.
2. 250 c.c. volumetric flasks.
3. 10 c.c., 5 c.c. pipettes.
4. 50 c.c. graduated cylinder.

Solutions

Molybdic Acid Solution

125 grams of pure ammonium molybdate are dissolved without heat in about 2 liters of phosphate-free distilled water. 75 c.c. of conc. H_2SO_4 are

slowly added and the volume made up to 2½ liters (roughly). A slight blue coloration does not hinder the use of this solution.

Hydroquinone Solution

50 grams of pure hydroquinone are dissolved in about 2½ liters of phosphate-free distilled water and 3 c.c. of conc. H_2SO_4 added.

Carbonate-Sulphite Solution

To 6 liters of distilled water add 1500 grams of commercial soda ash. Dissolve 225 grams of sodium sulphite in 1500 c.c. of water and add to the above solution.

Stock Solution of Phosphate

Pure mono-potassium phosphate is finely ground, dried at 105 deg. cent. for three hours, cooled and kept in desiccator. Of this salt 0.1432 grams are dissolved in distilled water, 5 c.c. of concentrated H_2SO_4 added and made up to one liter in a volumetric flask with distilled water. One c.c. of this solution contains one-tenth of a milligram of PO_4.

Sulphuric Acid Solution

300 c.c. of concentrated H_2SO_4 are added to about 2200 c.c. of distilled water. This is labeled H_2SO_4.

Determination of Phosphate

Three 250 c.c. volumetric flasks are required. Into the first, measure 50 c.c. of the filtered sample of boiler water. 10 c.c. of the standard phosphate solution are delivered by a pipette into the second flask, and 20 c.c. of the phosphate solution are delivered into the third flask. Add to each flask in succession, 10 c.c. sulfuric acid, 5 c.c. of molybdic acid and 5 c.c. of hydroquinone solution. Allow the reactions to proceed for five minutes. Add to each flask 15 c.c. of the carbonate sulphite solution. Agitate each flask to mix the reagents. Fill each flask to the 250 c.c mark with distilled water.

Place the flask containing the sample of boiler water between the two flasks containing the standard solutions and compare colors. If the color is lighter than the flask containing the 10 c.c., it is less than 20 p.p.m. of PO_4. If it is between the one containing the 10 c.c. and the one containing 20 c.c., it is between 20 and 40 p.p.m. If it is darker than the one containing 20 c.c., it is over 40 p.p.m.

Different maximum and minimum values may be established by changing the amount of standard phosphate solution used.

This method gives the PO_4 content with a possible error of about 10 per cent.

RECOMMENDED PRACTICES

Tests for Turbine Oils—Gravity

Signficance of Test

Gravity used in connection with other properties of the oil may serve as an index of uniformity of shipments. Gravity is of little significance as an index of the quality of the oil. The gravity of a petroleum oil is a numerical value which is an index of a measured volume of the product.

Method of Test

TENTATIVE METHOD OF TEST FOR GRAVITY BY MEANS OF THE HYDROMETER

Abstracted from A. S. T. M. Tentative Specification Serial Designation: D 287—28 T

ISSUED, 1928

DEFINITIONS

2. (*a*) *Specific Gravity.*—The specific gravity of a petroleum oil and of mixtures of petroleum products with other substances is the ratio of the weight of a given volume of the material at a temperature of 60 deg. fahr. (15.56 deg. cent.) to the weight of an equal volume of distilled water at the same temperature, both weights being corrected for the buoyancy of air.

(*b*) *A.P.I. Gravity.*—The A.P.I. gravity scale is an arbitrary one which is related to the specific gravity of a petroleum oil in accordance with the formula:

$$\text{Degrees A. P. I.} = \frac{141.5}{\text{sp. gr. } 60°/60° \text{ F.}} - 131.5$$

Table VIII showing the equivalent specific gravity, pounds per gallon and gallons per pound at 60 deg. fahr. for each degree A.P.I. from 0 to 100 deg. A.P.I. is given in the Appendix to this method.

APPARATUS

There are two kinds of hydrometers in common use, the plain type and the combined thermometer and hydrometer, known as a thermo-hydrometer. Although the thermo-hydrometer type of instrument is sufficiently satisfactory for routine use, the thermometer incorporated in it possesses certain inherent defects of design which render it unfit for use when results of unquestioned accuracy are desired. Therefore, in all referee tests the temperature of the sample being tested must be determined by means of a separate thermometer.

3. *Hydrometer Calibrations.*—The hydrometer may be calibrated either in terms of specific gravity or degree A.P.I. It shall be of glass of the conventional constant mass and variable displacement type, with a paper hand-written scale. The range may be any suitable portion of the interval between 0 and 100 deg. A.P.I. (1.0760 to 0.6112 sp. gr.) and it shall be so divided that 0.1 deg. A.P.I. or 0.0005 of a unit of specific gravity shall not be less than 1 mm. (0.039 in.) in width. The value of the smallest sub-divisions shall be 0.1 deg. A.P.I. when the instrument is calibrated in degrees A.P.I. or 0.0005 of a unit of specific gravity when it is calibrated in the specific gravity scale. The accuracy of calibration of the hydrometer shall be such that the error at any point of the scale shall not exceed the value of one smallest scale division. Each fifth smallest sub-division on the scale shall be denoted by a longer line. The graduations shall be numbered at each multiple of 1 deg. A.P.I. or at each multiple of 0.01 of a unit of specific gravity, in accordance with the type of calibration used. The paper scale, or an extension thereof, of the hydrometer shall have plainly printed on it the name of the manufacturer, a serial number and the definition of the scale.

NOTE.—In the case of A.P.I. hydrometers the scale is defined by the expression:

$$\text{Degrees A.P.I.} = \frac{141.5}{\text{sp. gr. } 60°/60° \text{ F.}} - 131.5$$

In the case of specific gravity hydrometers the inscription "Sp. gr. 60°/60° fahr., Petroleum" is sufficient to denote that the hydrometer is intended to determine specific gravities at 60 deg. fahr. relative to water at 60 deg. fahr. when the readings are taken at 60 deg. fahr.

The long axis of the hydrometer shall assume a vertical position when the instrument is floating freely in the sample. Any solid material, such as shot, paper, etc., used in the weighing of the hydrometer shall be firmly secured in place by the use of a suitable cement, the softening point of which lies well above 195 deg. fahr. When mercury is used for weighting, it shall be placed in a small bulb below the main bulb of the hydrometer and completely separated from the bulb by means of a glass partition.

4. (*a*) *Separate Thermometer.*—These specifications cover a total immersion thermometer graduated in either centigrade or fahrenheit degrees as specified, the ranges being — 20 + 102 deg. cent. or — 5 to + 215 deg. fahr. respectively.

Type: Etched stem, glass.

Liquid: Mercury.

Range and Subdivision: — 20 to + 102 deg. cent. in 0.2 deg. cent. or — 5 to + 215 deg. fahr. in 0.5 deg. fahr.

Total Length: 403 to 409 mm. (15.87 to 16.10 in.).

Stem: Plain front, enamel back, suitable thermometer tubing. Diameter 7 to 8 mm. (0.276 to 0.315 in.).

Bulb: Corning normal or equally suitable thermometer glass, heavy wall. Length 14 to 19 mm. (0.55 to 0.75 in.). Diameter 6 to 7 mm. (0.236 to 0.275 in.).

Distance to — 20 deg. cent. or — 5 deg fahr. Line from Bottom of Bulb: 32 to 51 mm. (1.26 to 2.00 in.).

Distance to + 102 deg. cent. or + 215 deg. fahr. Line from Top of Stem: 25 to 45 mm. (0.98 to 1.77 in.).

Filling Above Mercury: Nitrogen gas.

Top Finish: Glass ring.

Graduation: All lines, figures and letters clear cut and distinct. Each whole degree centigrade or fahrenheit line to be longer than the remaining lines. Graduations to be numbered at each multiple of 2 deg. cent. or 5 deg. fahr.

Immersion: Total.

Special Marking: "A. S. T. M. gr.," a serial number and the manufacturer's name or trade mark shall be etched on the stem.

Scale Error: The error at any point of the scale when the thermometer is standardized as provided below shall not exceed 0.1 deg. cent. or 0.25 deg. fahr.

Standardization: The thermometer shall be standardized immersed in the testing bath to the top of the mercury column, at the ice point and at temperature intervals of from 15 to 20 deg. cent. or 30 to 40 deg. fahr.

Case: The thermometer shall be supplied in a suitable case on which shall appear the marking: "A. S. T. M. gr. — 20 to + 102 deg. cent." or "A. S. T. M. gr — 5 to + 215 deg. fahr." according to the type of thermometer.

NOTE.—For the purpose of interpreting these specifications the following definitions apply:

The total length is the over-all length of the finished instrument.

The diameter is that measured with a ring gage.

The length of the bulb is the distance from the bottom of the bulb to the beginning of the enamel backing.

The top of the thermometer is the top of the finished instrument.

(*b*) *Thermometer for Thermo-hydrometer.*—The thermometer incorporated in the thermo-hydrometer type of instrument shall be of the paper scale type (scale to be placed in either the bulb or stem of the hydrometer) having a range of from 20 to 130 deg. fahr. or 60 to 220 deg. fahr. depending upon the range of the hydrometer. The paper scale shall be graduated in 2 deg. fahr. divisions accurate to ± 1 deg. fahr. (Note) and shall be printed in red ink to avoid any possibility of its being confused with the black gravity scale.

NOTE.—This approximates the limit of accuracy which it is possible to obtain in this type of thermometer. It becomes at once obvious, therefore, in view of the following facts, that a high degree of accuracy in the determination of the gravity of an oil cannot be expected when this type of thermometer is used for the determination of the temperature of the sample undergoing test.

Between 10 and 11 deg. A.P.I., 1 deg. A.P.I. is equivalent to 0.0070 of a unit of specific gravity. Between 90 and 91 deg. A.P.I., 1 deg. A.P.I. is equivalent to only 0.0028 of a unit of specific gravity. In correcting the observed gravity of an oil of 10 deg. A.P.I. for temperature, an error of ± 2 deg. fahr. in the determination of the temperature of the oil will introduce maximum error of only 0.1 deg. A.P.I. (0.0007 sp. gr.) in the gravity. In correcting the observed gravity of an oil of 90 deg. A.P.I. for temperature, an error of 1 deg. fahr. in the determination of the temperature of the oil will introduce a maximum error of 0.3 deg. A.P.I. (0.00084 sp. gr.) in the gravity. For convenience, the following table is given which shows the errors at each tenth degree A.P.I. from 10 to 100 deg. A.P.I. which may be introduced into a corrected gravity as the result of an error of ± 1 deg. fahr. in the determination of the observed temperature:

Observed Gravity, deg. A.P.I.	Resultant Maximum Error in Corrected Gravity, deg. A.P.I. per ± 1 °F. Error in Observed Temperature
10-11	0.1
20-21	0.1
30-31	0.1
40-41	0.1
50-51	0.2
60-61	0.2
70-71	0.2
80-81	0.2
90-91	0.3
At 99	0.3

5. *Hydrometer Cylinder.*—The hydrometer cylinder in which the sample for the gravity test is confined shall be made of clear glass and shall be cylindrical in shape. For convenience in pouring it may have a lip on the rim. The inside diameter of the cylinder shall be at least 2.54 cm. (1.0 in.) greater than the outside diameter of the hydrometer used in it. The height of the cylinder shall be such that the length of the column of sample it contains is greater by at least 2.54 cm. 1.0 in.) than the portion of the hydrometer which is immersed beneath the surface of the sample after a state of equilibrium has been reached.

PROCEDURE

6. (*a*) The determination of the gravity of crude petroleum or its products may be made at any suitable temperature between 0 and 195 deg. fahr. in accordance with the procedure described in Section 7. The observed gravity at the observed temperature shall be corrected to the gravity at 60 deg. fahr. as described in Section 8.

(*b*) The gravity of mixtures of petroleum products with other substances shall be determined at a temperature of 60 deg. fahr. in accordance with the procedure described in Section 7, since there are no nationally recognized tables giving the coefficients of expansion of such mixtures.

7. The sample to be tested for gravity shall be poured into the clean hydrometer cylinder without splashing, so as to avoid the formation of air bubbles and to reduce to a minimum the evaporation of the lower boiling constituents of the lighter oils. If air bubbles are formed they shall be removed after they have collected on the surface by touching them with a piece of clean blotting paper or filter paper before the hydrometer is placed in the sample. If the sample to be tested is easily volatile both the hydrometer and hydrometer cylinder shall be cooled before use to a temperature below that of the sample.

The cylinder containing the prepared sample shall be placed in a vertical position in a place free from air currents. The hydrometer shall be carefully lowered into the sample to a level, two smallest scale divisions below that at which it will float and shall then be released. When the hydrometer has come to rest, floating freely away from the walls of the cylinder, the gravity shall be read as the point at which the surface of the sample apparently cuts the hydrometer scale. In the case of samples sufficiently transparent this point shall be determined by placing the eye slightly below the level of the liquid and slowly raising it until the surface of the sample first seen as a distorted ellipse seems to become a straight line cutting the hydrometer scale. In the case of non-transparent samples where this procedure cannot be followed, the point on the hydrometer scale to which the sample rises above the main surface of the liquid shall be read with the eye placed slightly above the plane of the surface of the sample. This reading shall then be corrected by subtracting in the case of A.P.I. hydrometers or adding in the case of specific-gravity hydrometers, an amount equal to the height which the sample rises on the hydrometer stem above the main liquid surface. This height will vary for different oils and different hydrometers, and the amount of correction necessary will depend upon the width of the hydrometer scale graduations. The necessary correction factor shall be determined, therefore, for the particular hydrometer in use by observing the height above the main surface of the liquid to which the oil rises on the hydrometer scale when the hydrometer in question is immersed in a transparent oil having a surface tension similar to that of the sample under test.

The temperature of the sample shall be determined from the reading of the separate thermometer placed in the sample or from that of the thermometer contained in the hydrometer when the thermo-hydrometer type of instrument is used (see Note).

NOTE.—Precautions should, of course, be taken to prevent the temperature of the sample from changing appreciably during the time necessary to complete the test. This may be done when testing non-viscous oils by choosing a temperature of test only slightly different from the room temperature. When testing viscous oils which must be heated before testing it will be necessary to surround the test cylinder with a bath maintained at a constant desired temperature during the time of test.

Although it is usually satisfactory to determine the temperature of the sample immediately after reading the hydrometer, it is recommended that in all referee tests this temperature be determined both before and after the hydrometer is read.

CALCULATION

8. In the case of crude petroleum and petroleum products the determinations made in Section 7 are commonly referred to as "observed gravity and observed temperature." These observations shall be corrected to the gravity at 60 deg. fahr. by the use of Tables 1 and 3 of the "National Standard Petroleum Oil Tables" as published in the U. S. Bureau of Standards *Circular No.* 154. Table 1 shall be employed if the observed gravity is in degress A.P.I. and Table 3 if expressed as specific gravity.

Interpolations in Table 1 shall be made as follows: When the observed gravity ends in 1, 2, 3, 4 or 5 tenths of a degree A.P.I., find the degrees A.P.I. at 60 deg. fahr. corresponding to the observed gravity, disregarding the tenths of a degree. To this value add tenths of a degree dropped from the observed gravity to obtain the corrected value of the gravity in degrees A.P.I. at 60 deg. fahr. When the observed gravity ends in 6, 7, 8 or 9 tenths find the degrees A.P.I. and 60 deg. fahr. corresponding to the next larger value of observed gravity in the table. Correct this figure by subtracting a number of tenths equal to the difference between the observed value and the next larger value.

ACCURACY

9. Duplicate determinations shall agree within 0.1 deg. A.P.I. or the equivalent thereof in units of specific gravity at the particular gravity being determined when the same hydrometer and thermometer are used in the tests.

Separate laboratories using different hydrometers and thermometers should obtain duplicate results agreeing within 0.5 deg. A.P.I. or the equivalent thereof in units of specific gravity at the particular gravity being determined.

APPENDIX·

Table VIII is primarily an abridgement of Table 5 of the "National Standard Petroleum Oil Tables" as published in the U. S. Bureau of Standards *Circular No.* 154, which contains similar data for each 0.1 deg. A.P.I. from 10 to 100 deg A.P.I., inclusive. The data for gravities from 0 to 9 deg. A.P.I., inclusive, have been added in order to extend the use of the A.P.I. gravity scale to petroleum oils having a specific gravity slightly greater than unity.

Flash and Fire Test

Significance of Test

The Flash point of a product may be defined as the temperature to which it must be heated in order to give off sufficient vapor to form an inflammable mixture with air.

The Fire point may be defined as the temperature to which a product be heated in order to burn continuously after the inflammable air-vapor mixture is once ignited.

The Flash point of the oil may serve as a rough indication of its tendency to vaporize; it is an index of fire hazard but is more generally employed for identification and classification of the oil.

Method of Test

STANDARD METHOD OF TEST FOR FLASH AND FIRE POINTS BY MEANS OF OPEN CUP

Abstracted from A. S. T. M. Specification Serial Designation: D 92—24

Scope

1. The open cup flash and fire test on all products except fuel oils and those having an open cup flash below 175 deg. fahr. shall be determined in the Cleveland Open Cup.

APPARATUS

2. The cup, Fig. 5, shall be supported by a metal plate ¼ in. (0.635 cm.) in thickness and 6 in. (15.24 cm.) in width, Fig. 6. The plate shall be of brass, cast iron, wrought iron or steel. In the center of the plate there shall be a plane depression 1/32 in. (0.079 cm.) in depth, and of just sufficient diameter to fit the cup. There shall be a circular opening 2 3/16 in. (5.50 cm.) in diameter, cut through the plate, centering with the center of the above-mentioned depression. The plate shall be covered with a sheet of hard asbestos board ¼ in. in thickness, and of the same shape as the metal plate. There shall be cut in the center of the asbestos board a circular hole just fitting the cup. Heat may be supplied from any convenient source. The use of a gas burner, electric heater, or alcohol lamp is permitted, but under no circumstances are products of combustion or free flame allowed to come up around the cup. The source of heat shall be centered under the opening in the plate and shall be of a type that will not produce local superheating. If a flame heater is used, it may be protected from drafts or excessive radiation by any suitable type of shield, that does not project above the level of the upper surface of the asbestos board.

3. The thermometer shall conform to the following requirements. These specifications cover a special thermometer graduated in either Centigrade or Fahrenheit degrees as specified, the ranges being — 6 to + 400 deg. cent., or + 20 to + 760 deg. fahr. respectively.

Type: Etched stem, glass.

Liquid: Mercury.

Range and subdivision: — 6 to + 400 deg. cent. in 2 deg. cent. or + 20 to + 760 deg. fahr. in 5 deg. fahr.

Total length: 303 to 307 mm. (11.92 to 12.08 in.).

Stem: Plain front, enamel back, suitable thermometer tubing. Diameter, 6.0 to 7.0 mm. (0.24 to 0.28 in.).

Bulb: Corning normal or equally suitable thermometric glass. Length, not over 13 mm. (0.51 in.). Diameter, not greater than stem.

Distance to — 6 deg cent. or 20 deg. fahr. line from bottom of bulb: 40 to 50 mm. (1.57 to 1.97 in.).

Distance to 400 deg. cent. or 760 deg. fahr. line from top of thermometer: 30 to 45 mm. (1.18 to 1.77 in.).

Filling above mercury: Nitrogen gas.

Top finish: Red glass ring.

---

* The data in this column are based upon apparent weights in air, the weight of one gallon of water at 60° F. in air being assumed to be 8.3282 lb. Consequently, a correction for the buoyancy of air is required in computing these figures from the specific gravities in the second column.

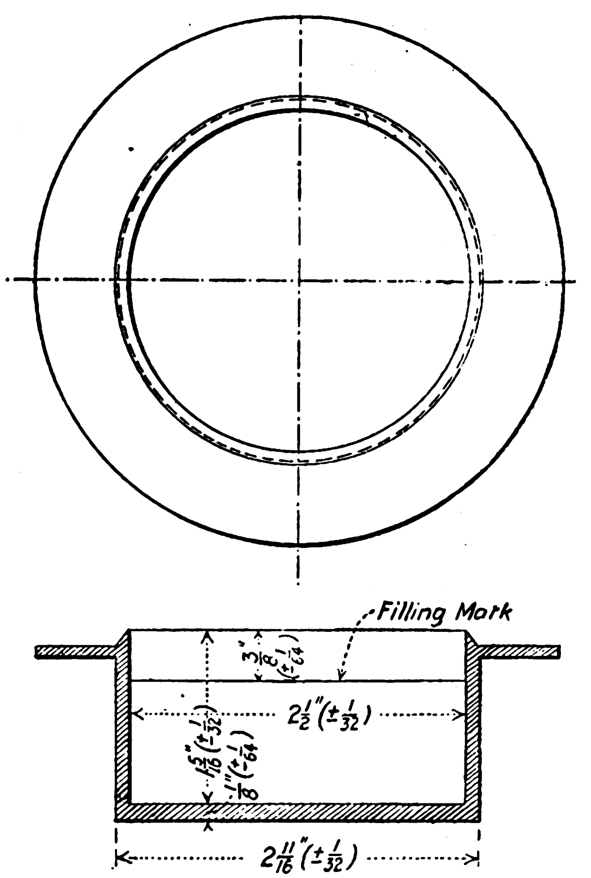

FIG. 5—CLEVELAND OPEN CUP, A.S.T.M.

Graduation: All lines, figures, and letters clear cut and distinct. The first and each succeeding 10 deg. fahr. line to be longer than the intermediate lines. Graduations to be numbered at each multiple of 20 deg.

Immersion: 25 mm. or one inch. The words "1-in. immersion" on Fahrenheit thermometers or "25 mm. immersion" on Centigrade thermometers and a line around the stem 25.4 mm. or 1.00 in. above the bottom of the bulb shall be etched on the thermometer.

Special marking: "A.S.T.M. Open Flash" a serial number and the manufacturer's name or trade mark shall be etched on the stem.

Scale error: The error at any point of the scale when the thermometer is standardized as provided below shall not exceed 1 deg. cent. up to 372 deg. cent. or 2½ deg. fahr. up to 700 deg. fahr.

Standardization: The thermometer shall be standardized at the ice point and at intervals of approximately 100 deg. fahr. for 25-mm. or 1-in. immersion and for the following temperatures of the emergent mercury column:

Thermometer Reading		Average Temperature of Emergent Mercury Column	
100° C.	200° F.	44° C.	110° F.
150° C.	300° F.	54° C.	129° F.
200° C.	400° F.	64° C.	150° F.
250° C.	500° F.	77° C.	175° F.
300° C.	600° F.	91° C.	205° F.
350° C.	700° F.	108° C.	240° F.

Test for permanency of range: After being subjected to a temperature between 360 to 370 deg. cent. or 680 to 700 deg. fahr. for 24 hours, the accuracy shall be within the limit specified.

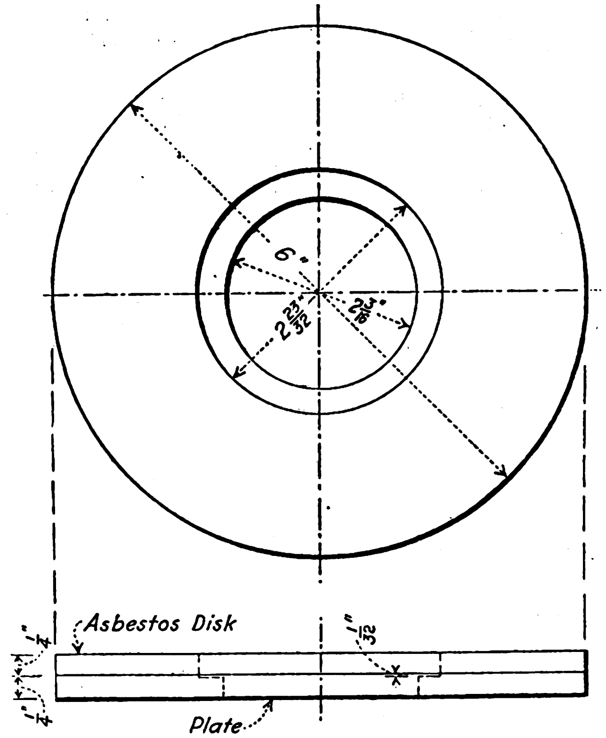

FIG. 6—HEATING PAD FOR CLEVELAND OPEN CUP, A.S.T.M.

Case: The thermometer shall be supplied in a suitable case on which shall appear the marking: "A.S.T.M. Open Flash, — 6 to + 400 deg. cent." or "A.S.T.M. Open Flash, + 20 to + 760 deg. fahr.," according to the type of thermometer.

NOTE.—For the purpose of interpreting these specifications the following definitions apply:
The total length is the over-all length of the finished instrument.
The diameter is that measured with a ring gage.
The length of the bulb is the distance from the bottom of the bulb to the beginning of the enamel backing.
The top of the thermometer is the top of the finished instrument.

PROCEDURE

4. (*a*) The thermometer shall be suspended or held in a vertical position by any suitable device. The bottom of the bulb shall be ¼ in. (0.635 cm.)[1] from the bottom of the cup, and above a point half way between the center and back of the cup.

(*b*) The cup shall be filled with the oil to be tested in such a manner that the top of the meniscus is exactly at the filling line at room temperature. The surface of the oil shall be free from bubbles. There shall be no oil above the filling line or on the outside of the apparatus.

(*c*) The test flame shall be approximately 5/32 in. (0.397 cm.) in diameter.

NOTE: For purposes of comparison it is recommended that a bead of suitable light colored material be mounted in a convenient position so that the size of the test flame can be determined. The device for applying the flame may be of any suitable type, but it is suggested that the tip be approximately 1/16 in. (0.159 cm.) in diameter at the end, and that the orifice be 1/32 in. (0.079 cm.) in diameter. If the device for operating the test flame be mounted in such a manner as to permit automatic duplication of the sweep of the test flame the radius of swing shall be not less than 6 in.

(*d*) The test flame shall be applied as the temperature read on the thermometer reaches each successive 5 deg. fahr. mark. The flame shall pass in a straight line (or on the circumference of a circle having a radius of at least 6 in.) across the center of the cup and at right angles to the diameter passing through the thermometer. The test flame shall, while passing across the surface of the oil, be in the plane of the upper edge of the cup. The time for the passage of the test flame across the cup shall be approximately one second.

---

[1] The immersion line engraved on the thermometer stem will be 1/16 in. (0.159 cm.) below the level of the rim of the cup.

(*e*) The oil shall be heated at a rate not exceeding 30 deg. fahr. per minute temperature rise, till a point is reached approximately 100 deg. fahr. below the probable flash point of the oil. Thereafter the rate of heating shall be decreased and for at least the last 50 deg. fahr. before the flash point is reached, the rate shall be not less than 9 nor more than 11 deg. fahr. per minute.

Flash Point

5. The flash point shall be taken as the temperature read on the thermometer when a flash appears at any point on the surface of the oil. The true flash must not be confused with a bluish halo that sometimes surrounds the test flame.

Fire Point

6. After determining the flash point, the heating shall be continued at the specified rate of 9 to 11 deg. fahr. per minute, and application of the test flame shall be made at the specified intervals until the oil ignites and continues to burn for a period of at least 5 seconds. The method of application of the flame shall be the same or for flash point. The temperature read at the time of the flame application which causes burning for a period of 5 seconds or more shall be recorded as the fire point.

Precautions

7. The flash point and fire point tests shall be made in a room or compartment free from air drafts. The operator shall avoid breathing over the surface of the oil. It is desirable that the room or compartment be darkened sufficiently so that the flash may be readily discernible.

Pour Point

Significance of Test

The pour point of a petroleum oil is the lowest temperature at which the oil will pour or flow when it is chilled without disturbance under certain definite specified conditions.

The pour point gives an indication of the temperature below which it may not be possible to pour or remove an oil from its container, or below which it might be dangerous to use the oil in gravity lubricating system, where the head tending to produce flow is small.

Method of Test

The Committee has deleted the procedure for cloud point as described in the A. S. T. M. Method D-97-28.

STANDARD METHOD OF TEST FOR POUR POINTS OF PETROLEUM PRODUCTS

Abstracted from A. S. T. M. Specification Serial Designation: D 97—28

Pour Point

1. The Pour Point of a petroleum oil is the lowest temperature at which this oil will pour or flow when it is chilled without disturbance under certain definite specified conditions.

2. The test for pour point shall be used for all other petroleum oils and may be used for oils on which the test for cloud point is permitted.

APPARATUS

Test Jar

3. The test jar, *a*, shall be of clear glass, cylindrical form, flat bottom, approximately 1 3/16 to 1 5/16 in. in inside diameter and 4½ to 5 in. high. An ordinary 4-oz. oil sample bottle may be used if it is within the above specifications, and no test jar is available.

4. The thermometer, *b*, shall conform to the requirements of one of the following specifications:

(*a*) These specifications cover a special thermometer graduated in either Centigrade or Fahrenheit degrees as specified, the ranges being — 38 to + 50 deg. cent. or — 36 to + 120 deg. fahr., respectively.

Type: Etched stem, glass.

Liquid: Mercury.

Range and Subdivision: — 38 to + 50 deg. cent. in 1 deg. cent. or — 36 to + 120 deg. fahr. in 2 deg. fahr.

Total Length: 220 to 224 mm. (8.69 to 8.81 in.).

Stem: Plain front, enamel back, suitable thermometer tubing. Diameter, 7.0 to 8.0 mm. (0.28 to 0.31 in.).

Bulb: Corning normal or equally suitable thermometric glass. Length, not over 9.5 mm. (0.37 in.). Diameter, not greater than stem.

Distance to — 38 deg. cent. or — 36 deg. fahr. Line from Bottom of Bulb: 120 to 130 mm. (4.73 to 5.12 in.).

Distance to + 49 deg. cent. or + 120 deg. fahr. Line from Top of Thermometer: 19 to 25 mm. (0.75 to 0.98 in.).

Expansion Chamber: To permit heating to 100 deg. cent. or 212 deg. fahr.

Filling Above Mercury: Nitrogen gas.

Top Finish: Plain.

Graduation: All lines, figures and letters clear cut and distinct. Lines at multiples of 5 deg. cent. or 10 deg. fahr. to be longer than the remaining lines. Graduations to be numbered at each multiple of 10 deg. cent. or 20 deg. fahr.

Immersion: 108 mm. or 4¼ in. The words "108-mm. immersion" on Centigrade thermometers or "4¼-in. immersion" on Fahrenheit thermometers and a line around the stem 108.0 mm. or 4.25 in. above the bottom of the bulb shall be etched on the thermometer.

Special Marking: "A.S.T.M. Cloud and Pour," a serial number and the manufacturer's name or trade mark shall be etched on the stem.

Scale Error: The error at any point of the scale, when the thermometer is standardized as provided below, shall not exceed 0.5 deg. cent. or 1 deg. fahr.

Standardization: The thermometer shall be standardized at the ice point and at intervals of approximately 20 deg. cent. or 40 deg. fahr. for 108-mm. or 4¼-in. immersion and for an average temperature of 21 deg. cent. or 70 deg. fahr. for the emergent mercury column.

Case: The thermometer shall be supplied in a suitable case on which shall appear the marking: "A.S.T.M. Cloud and Pour, — 38 to + 50 deg. cent." or "A.S.T.M. Cloud and Pour, — 36 to + 120 deg. fahr." according to the type of thermometer.

NOTE: For the purpose of interpreting these specifications the following definitions apply:
The total length is the over-all length of the finished instrument.
The diameter is that measured with a ring gage.
The length of the bulb is the distance from the bottom of the bulb to the beginning of the enamel backing.
The top of the thermometer is the top of the finished instrument.

(*b*) These specifications cover a special low cloud and pour test thermometer graduated in either centigrade or Fahrenheit degrees as specified, the ranges being — 60 to + 20 deg. cent. or — 70 to + 70 deg. fahr.

Type: Etched stem, glass.

Liquid: Toluene or other suitable liquid colored red with a permanent dye.

Range and Subdivision: — 60 to + 20 deg. cent. in 1 deg. cent. or — 70 to + 70 deg. fahr. in 2 deg. fahr.

Total Length: 227 to 231 mm. (8.92 to 9.08 in.).

Stem: Plain front, enamel back, suitable thermometer tubing. Diameter 7.0 to 8.0 mm. (0.28 to 0.31 in.).

Bulb: Corning normal or equally suitable thermometric glass. Length, 8.0 to 9.5 mm. (0.31 to 0.37 in.). Diameter, 5.0 to 6.5 mm. (0.22 to 0.26 in.).

Distance to — 57 deg. cent. or — 70 deg. fahr. Line from Bottom of Bulb: 120 to 130 mm. (4.73 to 5.12 in.).

Distance to + 20 deg. cent. or + 68 deg. fahr. Line from Top of Thermometer: 35 to 45 mm. (1.38 to 1.77 in.).

Expansion Chamber: To permit heating to + 60 deg. cent. or + 140 deg. fahr.

Filling above Liquid: Gas under pressure.

Top Finish: Plain.

Graduation: All lines, figures and letters clear cut and distinct, lines at multiples of 5 deg. cent. or 10 deg. fahr. to be longer than the remaining lines. Graduations to be numbered at each multiple of 10 deg. cent. or 20 deg. fahr.

Immersion: 108 mm. (4¼ in.). The words "108-mm. immersion" on centigrade thermometers, or "4¼-in. immersion" on fahrenheit thermometers and a line around the stem 108 mm. (4.25 in.) above the bottom of the bulb, shall be etched on the thermometer.

Special Marking: "A.S.T.M. Low Cloud and Pour" a serial number and the manufacturer's name or trademark shall be etched on, the thermometer.

Scale Error: The error at any point of the scale when the thermometer is standardized as provided below, shall not exceed 1 deg. cent. or 2 deg. fahr.

Standardization: The thermometer shall be standardized at the ice point and at intervals of approximately 20 deg. cent. or 35 deg. fahr. for 108-mm. or 4¼-in. immersion, and for an average temperature of 21 deg. cent or 70 deg. fahr. for the emergent liquid column.

Case: The thermometer shall be supplied in a suitable case on which shall appear the marking "A.S.T.M. Low Cloud and Pour, — 60 to + 20 deg. cent. or "A.S.T.M. Low Cloud and Pour, — 70 to + 70 deg. fahr.", according to the type of thermometer.

NOTE: For the purpose of interpreting these specifications, the following definitions apply:

The total length is the over-all length of the finished instrument.
The diameter is that measured with a ring gage.
The length of the bulb is the distance from the bottom of the bulb to the beginning of the enamel backing.
The top of the thermometer is the top of the finished instrument.

Cork

5. The cork, *c*, shall fit the test jar, and shall be bored centrally to take the test thermometer.

Jacket

6. The jacket, *d*, shall be of glass or metal, shall be water tight, of cylindrical form, flat bottom, about 4½ in. deep, with inside diameter ⅜ to ½ in. greater than outside diameter of the test jar.

Cork Disk

7. A disk of cork or felt, *e*, ¼ in. thick and of the same diameter as the inside of the jacket will be required.

Gasket

8. The ring gasket, *f*, shall be about 3/16 in. thick, and made to fit snugly around the outside of the test jar and loosely inside the jacket. This gasket may be made of cork, felt or other suitable material, elastic enough to cling to the test jar and hard enough to hold its shape. The purpose of the ring gasket is to prevent the test jar from touching the jacket.

9. The cooling bath, *g*, shall be of a type suitable for obtaining the required temperatures. The size and shape of the bath are optional but a support, suitable for holding the jacket firmly in a vertical position, is essential. For determination of very low pour points, a smaller insulated cooling bath may be used and the test jar placed directly in it. The required bath temperatures may be maintained by refrigeration if available, otherwise by suitable freezing mixtures.

NOTE.—The freezing mixtures commonly used are as follows:

For temperatures down to 50 deg. fahr., ice and water.
For temperatures down to 10 deg. fahr., crushed ice and sodium chloride.
For temperatures down to — 15 deg. fahr., crushed ice and calcium chloride crystals.
For temperatures down to — 70 deg. fahr., solid carbon dioxide and acetone or gasoline.

The last named mixtures may be made as follows: In a covered metal beaker chill a suitable amount of acetone or gasoline to 10 deg. fahr., or lower, by means of an ice-salt mixture. Invert a cylinder of liquid carbon dioxide and draw off carefully in a chamois skin bag the desired amount of carbon dioxide, which through rapid evaporation will quickly become solid. Then add to the chilled acetone or gasoline enough of the solid carbon dioxide to give the desired temperature.

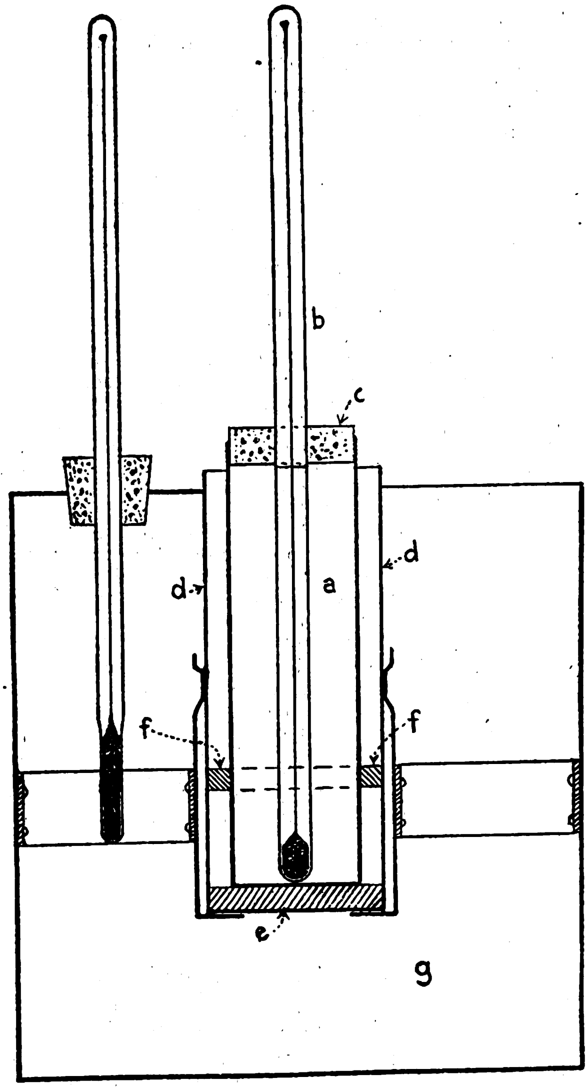

FIG. 7—APPARATUS FOR POUR TEST, A.S.T.M.

PROCEDURE FOR POUR POINT

10. The oil shall be poured into the test jar, *a*, to a height of not less than 2 nor more than 2¼ in. The jar may be marked to indicate the proper level. When necessary, the oil shall be heated in a water bath just sufficiently for pouring into the test jar.

The test jar shall be tightly closed by the cork, *c*, carrying the test thermometer, *b*, in a vertical position in the center of the jar with the thermometer bulb immersed so that the beginning of the capillary shall be ⅛ in. below the surface of the oil.

Heat without stirring to a temperature of 115 deg. fahr. in a bath maintained at not higher than 118 deg. fahr. The oil shall then be cooled to 90 deg. fahr. in air or in a water bath approximately 77 deg. fahr. in temperature. Oils with which the low cloud and pour test thermometer can be used from the beginning of the test shall be cooled to 60 deg. fahr. in any convenient manner before the thermometer is placed in position.

The disk, *e*, shall be placed in the bottom of the jacket, *d*, and the test jar, with the ring gasket, *f*, 1 in. above the bottom, shall be inserted into the jacket. The disk, gasket and inside of jacket shall be clean and dry.

After the oil has cooled enough to allow the formation of paraffin wax crystals, great care shall be taken not to disturb the mass of the oil nor to permit the thermometer to shift in the oil. Any disturbance of the spongy network of wax crystals will lead to low and fictitious results.

The temperature of the cooling bath, *g*, shall be adjusted so that it is below the pour point of the oil by not less than 15 nor more than 30 deg. fahr. and this temperature shall be maintained throughout the test. The jacket, containing the test jar, shall be supported firmly in a vertical position in the cooling bath so that not more than 1 in. of the jacket projects out of the cooling medium.

Beginning at a temperature 20 deg. fahr. before the expected pour point, at each test thermometer reading which is a multiple of 5 deg. fahr., the test jar shall be removed from the jacket carefully and shall be tilted just enough to ascertain whether there is a movement of the oil in the test jar. The complete operation of removal and replacement shall require not more than three seconds. As soon as the oil in the test jar does not flow when the jar is tilted, the test jar shall be held in a horizontal position for exactly five seconds, as noted by a stop watch or other accurate timing device and observed carefully. If the oil shows any movement under these conditions, the test jar shall be immediately replaced in the jacket and the same precedure repeated at the next temperature reading 5 deg. fahr. lower.

The test shall be continued in this manner until a point is reached at which the oil in the test jar shows no movement when the test jar is held in a horizontal position for exactly five seconds. Certain lubricating oils tend to move as a whole and should be very closely observed. The reading of the test thermometer at this temperature, corrected for error if necessary, shall be recorded. The pour point shall be taken as the temperature 5 deg. fahr. above this solid point.

Viscosity

Signficance of Test

Viscosity is the most important single property of a turbine oil. In a bearing operating properly, with a fluid film separating the surfaces, the viscosity of the oil at the operating temperature is the property which determines the bearing friction, heat generation and the rate of flow under given conditions of load, speed and bearing design. The oil should be viscous enough to maintain a fluid film between the bearing surfaces, in spite of the pressure tending to squeeze it out. While a reasonable factor of safety is essential, excessive viscosity means unnecessary friction and heat generation.

Viscosity is the measure of resistance to flow. In scientific work, viscosity is measured in terms of a unit of force designated as the "poise," while in most commercial work, an expression involving the time required for a measured volume of oil to flow, under specified conditions, through a carefully standardized tube, is known as the viscosity of the oil. To distinguish between these two methods of reporting results, the expression "absolute viscosity" is applied to an observation expressed in poises, while that expressed in terms of time of flow (Saybolt seconds by the above method) is designated as "viscosity" at a prescribed temperature.

[NOTE: The committee has deleted all references to the Saybolt Furol Viscosimeter which is included in the A.S.T.M. Standard Method D-88-26.]

Method of Test

STANDARD METHODS OF TEST FOR VISCOSITY OF PETROLEUM LUBRICANTS

Abstracted from A.S.T.M. Specification Serial Designation: D 88—26

Choice of Instrument

1. (*a*) Viscosity shall be determined by means of the Saybolt Universal Viscosimeter.

(*b*) In general, the Saybolt Universal Viscosimeter shall be used for lubricants.

TABLE IX—DIMENSIONS OF OIL TUBE

Dimensions	Saybolt Universal Viscosimeter		
	Minimum, cm.	Normal, cm.	Maximum, cm.
Inside diameter of outlet tube	0.1750	0.1765	0.1780
Outside diameter of outlet tube at lower end	0.28	0.30	0.32
Length of outlet tube	1.215	1.225	1.235
Height of overflow rim above bottom of outlet tube	12.40	12.50	12.60
Outside diameter of overflow rim, at the top[b]	[a]	......	3.30
Diameter of container	2.955	2.975	2.995
Depth of cylindrical part of container	8.8	......	......
Diameter of container between bottom of cylindrical part of container and top of outlet tube	0.9	......	......

[a] The minimum value shall preferably be not less than 3.2 cm.

[b] The section of overflow rim shall be bounded by straight lines, except that a fillet is permissible at the junction with the bottom of the gallery.

(*c*) The Saybolt Universal Viscosimeter shall not be used for times of flow less than 32 seconds.

I. APPARATUS

Viscosimeters

2. (*a*) The Saybolt viscosimeters (see Fig. 8) are made entirely of metal. The oil tube, *A*, is fitted at the top with an overflow cup, *B*, and the tube is surrounded by a bath. At the bottom of the oil tube is a small outlet tube through which the oil to be tested flows into a receiving flask, Fig. 9, whose capacity at 20 deg. cent. (68 deg. fahr.) to a mark on its neck is 60, ± 0.15, c.c. The outlet tube is of hard and non-corrosive metal such as stainless steel, monel metal, etc. The inside diameter of neck of flask, at the level where the graduation mark is placed, is 0.8 to 1.1 cm. The lower end of the outlet tube is enclosed by a larger tube, which when stoppered by a cork, *C*, acts as a closed air chamber and prevents the flow of oil through the outlet tube until the cork is removed and the test started. A looped string may be attached to the lower end of the cork as an aid to its rapid removal. The temperatures in the oil tube and in the bath are shown by thermometers. The bath may be heated by any suitable means. The oil tube shall be thoroughly cleaned, and all oil entering the oil tube shall be strained through a 100-mesh wire strainer. A stop watch shall be used for taking the time of flow of the oil and a pipette shall be used for draining the overflow cup.

Oil Tube

(*b*) The oil tubes, which may be standardized by the U. S. Bureau of Standards, shall conform to the dimensions given in Table IX. The time of flow shall be within ± 1 per cent of the time as obtained with the Bureau of Standards' master tube.[1]

---

[1] This tube represents the average mechanically perfect tube, based on the A. S. T. M. specifications, and has been approved by the American Petroleum Institute Committee on Viscosity Standards.

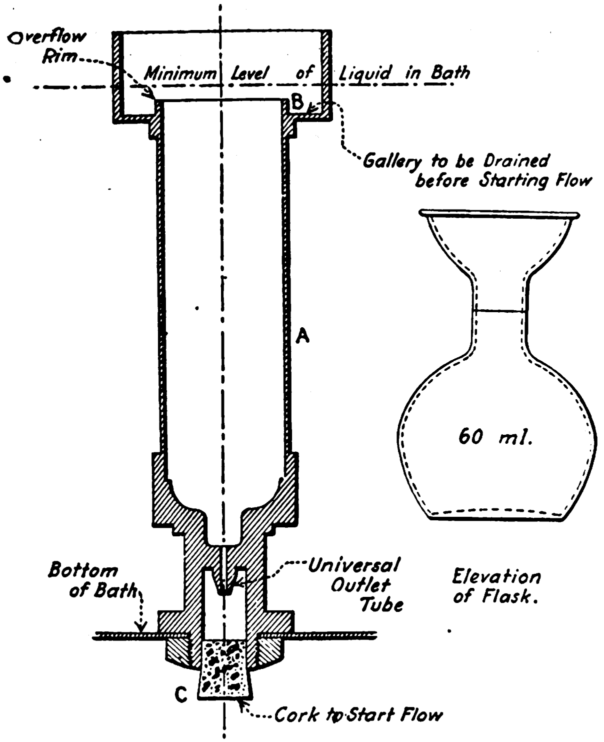

FIG. 8—Sectional View of Saybolt Standard Oil Tube, A.S.T.M.
FIG. 9—Saybolt Oil Receiving Flask, A.S.T.M.

Thermometers

(*c*) The bath and oil tube thermometers shall conform to the following requirements. They cover two sets of 4 thermometers each, one set being graduated in fahrenheit degrees and the other set in centigrade degrees, the ranges being chosen to include the temperatures commonly used in testing.

Type: Etched stem, glass.
Liquid: Mercury.
Ranges and Subdivisions:

Range 94-108° F., subdivision in 0.2° F. for tests at 100° F.
Range 204-218° F., subdivision in 0.2° F. for tests at 210° F.

or

Range 34- 42° C., subdivision in 0.1° C. for tests at 40° C.
Range 95-103° C., subdivision in 0.1° C. for tests at 100° C.

Total Length: 252 to 256 mm. (9.92 to 10.08 in.).

Stem: Plain front, enamel back, suitable thermometer tubing. Diameter, 6 to 7 mm. (0.236 to 0.275 in.). The stem shall preferably be made with an enlargement not less than 4 nor more than 7 mm. (0.16 to 0.28 in.) in length, having a diameter 2 to 3 mm. (0.08 to 0.12 in.) greater than that of the stem, the bottom of the enlargement being 114 mm. (4.5 in.) above the bottom of the bulb.

Bulb: Corning normal or equally suitable thermometric glass.

Length, 25 to 35 mm. (1.0 to 1.4 in.).

Diameter, not less than 5 mm. (0.197 in.) and not greater than that of stem.

Distance to Lowest Specified Graduation from Bottom of Bulb: 135 to 150 mm. (5.3 to 5.9 in.).

Distance to Highest Specified Graduation from Top of Stem: 20 to 35 mm. (0.8 to 1.4 in.).

Contraction Chamber: To be of long narrow type, top to be not more than 60 mm. (2.36 in.) above bottom of bulb, mercury to stand in contraction chamber at 32 deg. fahr. (0 deg. cent.).

Expansion Chamber: To permit heating the thermometer 90 deg. fahr. (50 deg. cent.) above highest temperature on scale, and in all cases to permit heating to 212 deg. fahr. (100 deg. cent.).

Filling above Mercury: Nitrogen gas.

Top Finish: Glass ring.

Graduation: All lines, figures and letters clear cut and distinct. The first and each succeeding 1 deg. fahr. or 0.5 deg. cent. line to be longer than the remaining lines. Graduations to be numbered at each multiple of 2 deg. fahr. or 1 deg. cent.

Immersion: Total.

Special Marking: "A.S.T.M." Viscosity test points to be numbered in full figures and in red, other graduations and figures in black. A serial number and the manufacturer's name or trademark shall be etched on the stem.

Scale Error: The error at any point of the scale shall not exceed 0.2 deg. fahr. (0.1 cent.).

Standardization: The thermometers are to be standardized for the condition of total immersion. Correction for emergent stem shall not be applied.

Case: Each thermometer shall be supplied in a suitable case on which shall appear the marking, "A.S.T.M. Saybolt Viscosimeter Thermometer" and the range.

II. TEMPERATURE OF TESTING

3. (*a*) With the Saybolt Universal viscosimeter, determinations shall be made at 100 deg. fahr. (37.8 deg. cent.), and 210 deg. fahr. (98.9 deg. cent.).

(*b*) Viscosities shall be expressed as ...... seconds, Saybolt Universal, being the time in seconds for the delivery of 60 c.c. of oil.

III. PROCEDURE

4. In tests at 100 deg. fahr. (37.8 deg. cent.) the bath temperature throughout the test shall not vary more than ± 0.1 deg. fahr (0.06 deg. cent.) from the predetermined temperature which will maintain thermal equilibrium as long as the oil is well stirred with the thermometer. In tests at 210 deg. fahr. (98.9 deg. cent.) a variation of ± 0.2 deg. fahr. (0.11 deg. cent.) is permitted.

Any construction of bath may be employed provided the bath temperature necessary to maintain thermal equilibrium (while the oil in the oil tube is well stirred by the oil tube thermometer) is not in excess of 100.25 and 212.00 deg. fahr. (37.9 and 100.00 deg. cent.), respectively, for the standard temperatures previously mentioned. The level of the bath liquid shall not be lower than 0.5 cm. above the overflow rim of the oil tube. In tests at 210 deg. fahr. (98.9 deg. cent.) the water bath shall be vigorously stirred, and may be heated by the direct injection of steam near the bottom of the bath. A bath of other suitable liquid may be used provided it is properly heated and stirred.[1] The heating and stirring of the bath may be accomplished by any suitable means, provided the source of heat is not less than the following distances from any part of the oil tube: 2 in. (5 cm.) with an external heater, 1¼ in. (3 cm.) with an immersion heater. Viscosity determinations shall be made in a room free from daughts and from rapid changes in temperature. The room temperature shall be between 68 and 86 deg. fahr. (20 and 30 deg. cent.).[2]

All oil introduced into the oil tube, either for cleaning or for test, shall first be passed through the strainer.

To make the test, heat the oil to the necessary temperature and clean out the oil tube. Pour some of the oil to be tested through the cleaned tube. Insert the cork stopper into the lower end of the air chamber at the bottom of the oil tube, sufficiently to prevent the escape of air, but not to touch the small outlet tube.

---

[1] For example, the bath liquid may be water, to which glycerin or salt has been added. In ordinary routine testing it is frequently desirable to employ oil as a bath medium. This is allowable provided the temperature of the oil bath is adjusted so that the necessary condition of thermal equilibrium is maintained. It is usually necessary to maintain the oil bath at slightly higher temperatures than are necessary when water is the bath medium. Oil bath temperatures will need to be from 0.1 to 0.2° F. (0.06 to 0.11° C.) higher for tests at 100° F. (37.8° C.) and 1.5 to 2.0° F. (0.85 to 1.11° C.) higher for tests at 210° F. (98.9° C.) than the corresponding water bath temperatures.

[2] These limits are necessary for extreme accuracy in standardization and referee tests, but for routine purposes the use of higher temperatures up to 100° F. (37.8° C.) will not ordinarily cause an error of more than 1 per cent.

Heat the oil to be tested, outside the viscosimeter, to slightly but not more than 3 deg. fahr. (1.7 deg. cent.) above the temperature at which the viscosity is to be determined, and pour it into the oil tube until it ceases to overflow into the overflow cup. By means of the oil tube thermometer, keep the oil in the oil tube well stirred, and also stir well the liquid in the bath. It is extremely important that the temperature of the bath be maintained constant during the entire time consumed in making the test. After the temperature of the bath and of the oil in the oil tube have been constant for one minute at the desired temperatures, withdraw the oil tube thermometer, quickly remove the surplus oil from the overflow cup by means of a pipette[3] so that the level of the oil in the overflow cup is below the level of the oil in the oil tube proper; place the 60-c.c. flask, Fig. 9, in position so that the stream of oil from the outlet tube will strike the neck of the flask so as to avoid foam. Snap the cork from its position, and at the same instant start the stop-watch. Stir the liquid in the bath during the run and carefully maintain it at the previously determined proper temperature. Stop the watch when the bottom of the meniscus of the oil reaches the mark on the neck of the receiving flask.

The time in seconds for the delivery of 60 c.c. of oil is the Saybolt Universal viscosity of the oil at the temperature at which the test is made.

With proper attention to details of methods of procedure, duplicate results should not differ from each other by more than 1 per cent.

Steam Emulsion

Significance of Test

When oil and water are mixed in any manner, standing causes them to separate more or less rapidly. The presence of small amounts of certain other materials decreases the rate of separation and may prevent any separation whatever. This physical condition is known as an emulsion, and the phenomenon is known as emulsification.

The A. S. T. M. Standard Method of Test for Steam Emulsion of Lubricating Oils, D-157-28, is designed for use in oils whenever a knowledge of the tendency to separate from water is required.

For forced-feed circulating lubrication systems where the oil is likely to come in contact with water or steam, the steam emulsion test is of great importance. This is particularly true of steam-turbine lubricating systems. For oils intended for this type of service the use of a test of this kind is thoroughly established. Next to viscosity, it is considered the most important test for steam turbine oils, since rapid separation from water is an essential characteristic.

For the lubrication of steam turbines, it is very essential that any emulsion which may be formed separate rapidly and completely. Accordingly a knowledge of the rapidity with which the constituents of an emulsion of oil and water will separate is of considerable value. Since it is not possible to duplicate service conditions in the laboratory, it is necessary to measure the rapidity of separation under some arbitrarily selected set of conditions. This is expressed in some numerical form which serves as an index of the emulsifying characteristics of the oil.

Steam is passed into the oil under specified conditions and the time in seconds required for complete separation of the oil and condensed steam is recorded as the Steam Emulsion Number (S. E. Number) of the oil.

Method of Test

STANDARD METHOD OF TEST FOR STEAM EMULSION OF LUBRICATING OILS

Abstracted from A. S. T. M. Specification Serial Designation: D 157—28

Scope

1. This method shall be used on all oils when an emulsion, demulsibility or emulsification test is required.[1] This method is commonly used for turbine oils and may be used for other lubricating oils.

Description

2. The Steam Emulsion Number (A.S.T.M.S.E.) is the number of seconds required for an oil to separate when emulsified and separated under definitely prescribed conditions.

APPARATUS

Steam Generator

3. The steam generator shall be made of either metal or glass of at least one-liter capacity, capable of withstanding the heat necessary for continued use in the production of steam. It shall be fitted with three outlets with suitable connections for rubber tubing. In case of a metal generator, a large opening for filling and a suitable water gage shall be a necessary part of the apparatus.

Baths

4. The baths shall be of glass with a capacity of 3 to 3½ liters and a depth of 7½ to 9 in. A good quality battery jar or beaker is entirely satisfactory.

Source of Heat

5. Heat for the steam generator shall be supplied by a suitable gas burner or electric hot plate. The separating bath may be heated by any convenient means, including an auxiliary steam line as shown in Fig. 10.

Oil Container

6. The oil container shall be a 25 by 200-mm. test tube graduated from zero or from 10 to 50 c.c. in cubic centimeters, each even 5-c.c. line to encircle the tube.

Steam Piping

7. The steam piping or the steam delivery tube shall consist of a piece of thin-wall glass tubing, not less than 2.3 nor more than 2.7 mm. in inside diameter and 12 in. in length. The steam pipe shall be cut off diagonally at an angle of 30 deg. with the axis of the tube at the discharge orifice and shall be bent at right angles 10 in. from the discharge orifice.

Accessories

8. Accessories shall consist of:

(*a*) Suitable wooden or metal frames or holders for holding all containers in a vertical position in the baths;

(*b*) Thermometers for the separating and emulsifying baths (floating type thermometers of suitable range);

(*c*) Thermometers for the oil container tube (engraved-stem type, of suitable range, graduated in 1 deg. fahr., 5 to 7 mm. in diameter);

(*d*) Corks, rubber tubing and screw pinch-cocks.

---

[3] It is recommended that the tip of the pipette should be about 2 mm. inside, and about 3 mm. outside diameter, and great care should be exercised to avoid touching the overflow rim while draining the overflow cup.

[1] Methods for sampling are covered in the Tentative Methods of Sampling Petroleum and Petroleum Products (Serial Designation: D 270-27 T) of the American Society for Testing Materials, see 1928 Book of A.S.T.M. Tentative Standards. The following paragraphs, which are particularly important for protection of samples for the steam emulsion test, are quoted from these methods:

"34. (*a*) Corks for bottles shall be clean, free from holes and loose bits of cork.

(*b*) Sealing wax, or paraffin, shall *not* be poured over corks after cooling."

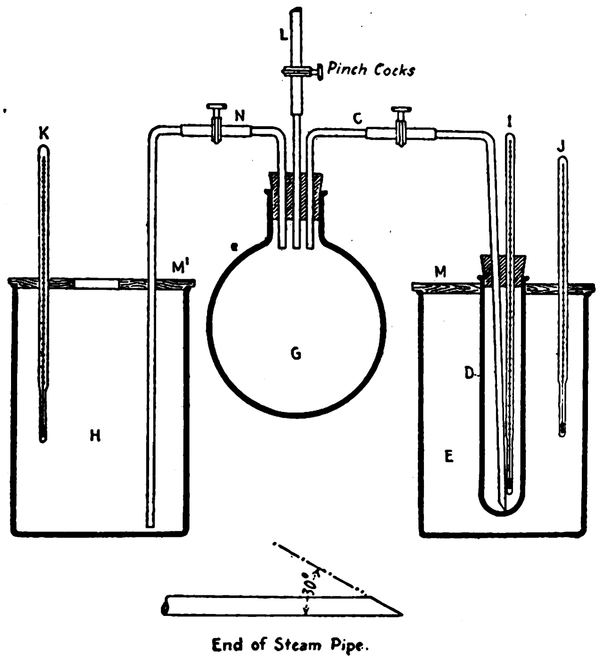

FIG. 10—APPARATUS FOR STEAM EMULSION TEST, A.S.T.M.

PROCEDURE

Preparation

9. The apparatus shall be assembled as shown in Fig. 1. The steam generator shall be filled one-half full of water and heat applied. The baths shall be filled with 3 liters ± 60 c.c. of water. The temperature in the separating bath shall be raised to and maintained at 200 to 203 deg. fahr.

NOTE: Care must be taken if glass battery jars are used, as direct heating by flame or electric heater may cause breakage.

The temperature of the emulsifying bath shall be brought to not less than 67 deg. fahr., nor more than 78 deg. fahr. at the start of the test, and is not controlled thereafter. Twenty cubic centimeters of the oil to be tested shall be measured in the oil container at room temperature and the latter placed in the holder of the emulsifying bath. The steam pipe, or delivery tube, shall be connected to the steam generator with suitable rubber tubing, and screw pinch-cocks placed as shown in Fig. 10.

Care should be taken to see that the apparatus particularly the oil container, oil container thermometer and the steam delivery tube are *chemically clean* before using. Care shall also be taken to prevent any foreign materials from entering the steam generator as any contamination of the steam renders the test valueless.

Emulsification

10. The steam delivery tube line shall be steamed out until all condensation disappears. A cork having two openings, with the thermometer in one, shall be placed in the mouth of the oil container. The thermometer shall be adjusted so that the bottom of the bulb is ¾ to 1 in. from the bottom of the oil container. The steam delivery tube shall be inserted through the second opening in the cork (Note.—This fitting shall be loose.) so that the end of the steam delivery tube shall touch the center of the bottom of the oil container. Steam shall be admitted at a rate that will maintain the temperature of the oil, as shown on the thermometer in the oil container, between 190 and 195 deg. fahr.

NOTE: The usual time necessary for the temperature of the oil to come to this point is 45 to 75 seconds, depending on its character.

This control shall be effected by manipulation of the pinch-cocks on the steam delivery line and steam exhaust line from the steam generator. The steam supply shall be sufficient at all times to cause a generous discharge from the exhaust line. Steaming shall be continued until the volume of condensed steam and oil in the oil container tube is 40 c.c. ±3 c.c. The time required for this operation shall be 4 to 6.5 minutes, depending on the quality of the oil, altitude, etc. If condensed water amounts to 20 c.c. in less than 4 minutes, it shall be taken as an indication of wet steam or incomplete steaming out of the line and the test shall be re-run.

NOTE: The apparent volume in the tube near the end of the steaming operation is approximately 12 to 15 cc. greater than the actual volume due to displacement caused by steam, thermometer and steam delivery tube.

Separation

11. The steam delivery tube shall be withdrawn as soon as the required volume is obtained. The oil container shall be transferred immediately to the separating bath which shall be maintained at 200 to 203 deg. fahr. It is extremely important that the temperature of the separating bath be maintained within the given limits. A stop-watch shall be started at the instant of withdrawal of the steam delivery tube. The cork containing the thermometer shall be removed after the oil container and contents have been placed in the separating bath. The contents of the oil container shall be examined at least every 30 seconds, and the volume of the separated oil layer shall be recorded. When this reading operation has continued until 20 c.c. of oil have separated, the elapsed time in seconds shall be reported as the Steam Emulsion Number (S.E. No. ....). No differentiation shall be made between clear and turbid oil. This examination shall be made without withdrawing the oil container and its contents from the separating bath, and reading the volumes.

In cases where the interface between more-or-less clear oil and the emulsion is not a clear, straight horizontal line, the position of such a line should be carefully estimated to the nearest 0.5 c.c.

If 20 c.c. of oil do not separate, the test shall be discontinued.

Interpretation

12. In interpreting results, the assumption shall be made that the rate of emulsion separation is directly proportional to the resistance to emulsification of the tested oil.

NOTE: The expansion of the oil at the higher temperature is disregarded, so when the separation of the oil is complete, as regards the interface between the oil and emulsion layers, the volume of separated oil will always be more than 20 cc. This in no way interferes with the reproducibility of results, and the time shall be recorded when 20 cc.—and not necessarily all—of the oil have separated, when this occurs in less than 20 minutes.

A.S.T.M. S.E. Number

13. Results shall be reported, to the nearest second, of the time necessary for 20-c.c. oil separation. The time in seconds shall be reported as the Steam Emulsion Number, A.S.T.M. Method (S.E. No.....). In cases where the required volume shall not have separated in 20 minutes, the oil shall be reported as having an S. E. Number, A.S.T.M. Method, of 1200 plus. If a duplicate determination varies by more than 10 per cent, a third test shall be made and the average of the three tests reported.

NOTE: Oils which emulsify separate into three layers without exception: top, clear or turbid oil; middle, lacy or creamy emulsion; bottom, clear or milky water. The S.E. Number is derived from the top layer.

Neutralization Number

Significance of Test

The Neutralization Number of an oil is defined as the weight in milligrams of potassium hydroxide required to neutralize one gram of oil. It represents the sum of the quantities of mineral and so-called organic acids present in the oil or the difference between the organic acidity and the alkali present in the oil. If, as is usually the case, no mineral acid or alkali is present in the oil, the neutralization number is directly proportional to "organic acidity."

The "Alkali Neutralization Number" is defined as the weight in milligrams of potassium hydroxide equivalent to the acid required to neutralize one gram of oil.

The "Mineral Acid Neutralization Number" is defined as the milligrams of potassium hydroxide required to neutralize the mineral acid content in one gram of oil.

The effect of alkali or mineral acid in turbine oil is deleterious.

Organic acids normally present in properly refined turbine oils are low in amount and are not considered harmful from a corrosive standpoint.

Method of Test

[NOTE: The Committee has deleted references to compounded oils, as published in A.S.T.M. Serial designation D-188-27T.]

TENTATIVE METHOD OF TEST FOR NEUTRALIZATION NUMBER OF LUBRICANTS

Abstracted from A.S.T.M. Specifications Serial Designation: D-188-27T

Scope

1. The methods described herein are designed to indicate in lubricants the presence of organic constituents having acid characteristics and the contamination by alkalies and mineral acids.

Definitions

2. (*a*) The Neutralization Number is the weight in milligrams of potassium hydroxide required to neutralize one gram of oil.

NOTE: The Neutralization Number expresses the total amount of the mineral acid, and of the organic constituents having acid characteristics.

(*b*) The Alkali Neutralization Number is defined as the weight of acid required to neutralize one gram of oil, expressed in equivalent milligrams of potassium hydroxide.

(*c*) The Mineral Acid Neutralization Number is the number of milligrams of potassium hydroxide required to neutralize the mineral acid content in one gram of oil.

SOLUTIONS REQUIRED

3. (*a*) *Aqueous Potassium Hydroxide* (1 c.c. = 5 mg. KOH).— Dissolve 5.1 g. of potassium hydroxide, c.p., in one liter of freshly boiled and cooled distilled water. Add a very small amount of barium hydroxide, sufficient to precipitate any potassium carbonate present. Standardize this solution against Bureau of Standards certified benzoic acid, using phenolphthalein as an indicator according to the relation:

$$\frac{5\text{ mg. KOH}}{x\text{ mg. benzoic acid}} = \frac{56.104\text{ g. KOH}}{122.048\text{ g. benzoic acid}}$$

$$1\text{ cc. of KOH} = 10.88\text{ mg. benzoic acid.}$$

This weight of benzoic acid is required for standardization. Make necessary adjustments so that the value of potassium hydroxide equals 5 mg. KOH per 1 cc.

NOTE: Fit the solution bottle with a guard tube of soda lime to prevent access of carbon dioxide. The solution should be standardized at necessary intervals.

The weight of benzoic acid should be dissolved in 50 cc. of 95-per cent alcohol and titrated cold. For blank, use same amount of alcohol and correct the titration.

(*b*) *Sulfuric Acid Solution* (1 cc. = 5 mg. KOH).—Match a sulfuric acid solution so that 1 cc. of the acid will be required to neutralize 1 cc. of the KOH, using phenolphthalein as an indicator, titrating in boiling solution.

(*c*) *Neutralized 95-per-cent Alcohol.*—Add a few drops of phenolphthalein and neutralize carefully the alcohol to a very faint pink end point with some of the above prepared alkali solution.

(*d*) *Phenolphthalein Indicator.*—Dissolve 10 g. of the indicator in 1 liter of 95-per-cent alcohol, preferably ethyl. Use 1 cc. of this strength for titration.

(*e*) *Methyl Orange Indicator.*—Dissolve 1 g. of the indicator in 1 liter of distilled water. Use 0.1 cc. of this strength for titration.

METHODS

4. *Method A.—Neutralization Number of Petroleum Products.*

Weight of Oil: Approximately 20 g. weighed to 0.1 g.

Volume of Solvent: 100 cc. of a mixture of 1:1 neutralized alcohol and distilled water.

Procedure: Agitate oil and solvent thoroughly and heat to boiling. Add 1 cc. of phenolphthalein indicator and titrate rapidly, with vigorous agitation, to a sharp pink end point. The titration must be completed in a hot solution, reheating same if found necessary.

The color change is noted in the alcohol water layer.

Calculation:

$$\frac{(\text{Cubic centimeters of KOH}) \times 5}{\text{Weight of oil taken}} = \text{mg. KOH per 1 g. of oil.}$$

5. *Method B.*[1]*—Alkali or Mineral Acid Neutralization Number in Petroleum Products.*

Weight of Oil: 25 to 50 g. weighed to 0.1 g.

Volume of Solvent: Boiling distilled water, 200 cc.

Procedure: Introduce into a 250-cc. separatory funnel 25 to 50 g. of oil weighed to 0.1 g., and add 100 cc. of boiling distilled water. Shake vigorously, and after oil and water have separated, drain the water layer into a 500-cc. casserole. Wash the oil in the separatory funnel twice by vigorously shaking with 50-cc. portions of boiling distilled water and after separation, drain into the casserole. To the accumulated 200 cc. of water add 1 drop of 1-per-cent phenolphthalein solution. Boil. If solution turns pink, add 1 cc. of the indicator and titrate with the sulfuric acid solution until the extraction is colorless.

If the addition of 1 drop of phenolphthalein causes no change in color, add 0.1 cc. of methyl orange. If color changes to red or pink, titrate with the KOH solution until the red color is just discharged.

An equal volume of distilled water shall be titrated with the standard solution used, and the amount of alkali or acid required shall be subtracted from the titration for blank correction.

Calculation: If the acid solution was required to discharge the phenolphthalein end point, the alkali neutralization number equals:

$$\frac{(\text{Cubic centimeters of acid}) \times 5}{\text{Weight of oil}}$$

If the alkali solution was required to discharge the methyl orange end point, the mineral acid neutralization number equals:

$$\frac{(\text{Cubic centimeters of alkali}) \times 5}{\text{Weight of oil}}$$

Corrosion Test

Significance of Test

Since turbine oils are used in contact with metals, it is essential that the metal shall not be corroded. Sulphur and corrosive compounds are sometimes present in turbine oils and in order to determine the corrosive nature of such oils a corrosion test is employed, which consists of immersing a piece of copper in the oil and maintaining the oil at a temperature of 212 deg. fahr. for three hours. Darkening of the copper after this treatment indicates the presence of corrosive compounds.

---

[1] When the oil is acid, the acidity shall not be reported as sulfuric or hydrochloric acid unless the presence of these acids shall have been confirmed by tests.

The above test (while only qualitative) affords the proper degree of protection to the user without imposing an unnecessary hardship on the manufacturer.

Method of Test

Copper strip.

Method 530,31 Bureau of Mines Technical Paper No. 323-B, 1927, p. 97.

Place a clean strip of mechanically polished pure sheet copper about 0.5 in. wide and 3 in. long in a clean test tube. Add enough of the sample to be tested completely to cover the strip. Close the tube with a vented stopper and maintain for 3 hr. at 212 deg. fahr. Rinse the copper strip with sulphur-free acetone and compare it with a similar strip of freshly polished copper. Discoloration or pitting indicates corrosion.

Water and Sediment Test

Significance of Test

This test when applied to new oil receipts gives a volumetric indication of water and of foreign materials such as rust from containers. This test when applied to serviced turbine oil permits the volumetric estimation of water and sediment (sludge) in suspension in the circulating oil.

Method of Test

STANDARD METHOD OF TEST FOR WATER AND SEDIMENT IN PETROLEUM PRODUCTS, BY MEANS OF CENTRIFUGE

Abstracted from A.S.T.M. Specification Serial Designation: D 96—28

Scope

1. This method may be used for crude mineral oils and fuel oils. A centrifuge method for "Water and Sediment" is not entirely satisfactory because the amount of water obtained is nearly always lower than the actual water content. Nevertheless, on account of the wide use of the centrifuge for this purpose, it is desirable that the method of making the determination be standardized as far as possible. It must be clearly understood that the reading of the centrifuge tube includes both the sediment and the precipitated water.

Sample

2. The sample shall be thoroughly representative of the material in question and the portion used for the test shall be thoroughly representative of the sample itself. Deviation from this rule shall not be permitted. The difficulties in obtaining representative samples for this determination are unusually great; hence, the importance of sampling cannot be too strongly emphasized.

APPARATUS

Centrifuge

3. The centrifuge shall be capable of whirling at the required speed at least two 100-cc. centrifuge tubes filled with water. It shall be of sound design and rugged construction so that it may be operated without danger. The tube carriers shall be so designed that the glass centrifuge tubes may be cushioned with water, rubber or other suitable material. The tube holders shall be surrounded during the operation by a suitable metal shield or case, strong enough to eliminate danger if any breakage occurs.

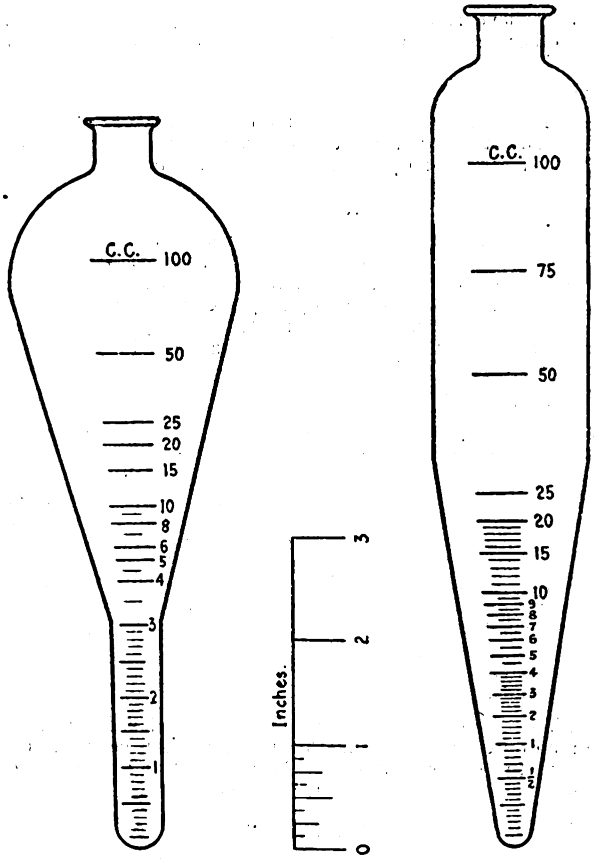

FIG. 11—CENTRIFUGAL TUBES, A.S.T.M.

The preferred form of centrifuge shall have a diameter of swing (tip to tip of whirling tubes) of 15 to 17 in. and a speed of at least 1500 r.p.m. or the equivalent. If the available centrifuge has a diameter of swing varying from these limits, it shall be run at the proper speed to give the same centrifugal force at the tips of the tubes as that obtained with the preferred form of centrifuge. The proper speed shall be calculated from the following formula in which d represents diameter of swing (tip to tip of whirling tubes) of the centrifuge used:

$$\text{R.p.m.} = 1500\sqrt{\frac{16}{d}}$$

Centrifuge Tubes

4. The centrifuge tubes, A.S.T.M. type shall be made of suitable glass and thoroughly annealed. The total capacity shall be about 125 cc. and the mouth shall be suitably constricted for closing with a cork. The graduations shall be clear and distinct, reading upward from the bottom of the tube. The value of the divisions for each range shall not be greater than shown in the following tabulation:

Range.	Scale Divisions.	Limit of Error.	Numbered.
0 - 3 cc.	0.1 cc.	0.05 cc.	1, 2, 3 cc.
3 - 5 "	0.5 "	0.2 "	4, 5 "
5 - 10 "	1.0 "	0.5 "	6, 8, 10 "
10 - 25 "	5.0 "	1.0 "	15, 20, 25 "
50 - 100 "	50.0 "	1.0 "	50, 100 "

The shape is optional provided it does not conflict with the other requirements. Satisfactory types are shown in Fig. 11.

Bath

5. The water or oil bath shall be of sufficient depth for immersing the centrifuge tubes in a vertical position to the 100-cc. mark. Means shall be provided for heating this bath to 120 deg. fahr.

PROCEDURE

6. (*a*) Exactly 50 cc. of 90-per-cent benzol shall be measured into each of two centrifuge tubes and exactly 50 cc. of the oil to be tested shall then be added to each. The centrifuge tubes shall be tightly stoppered and shall be shaken vigorously until the contents are thoroughly mixed. The temperature of the bath shall be maintained at 120 deg. fahr. and the centrifuge tubes shall be immersed therein to the 100-cc. mark for 10 minutes.

(*b*) The two centrifuge tubes shall then be placed in the centrifuge on opposite sides and shall be whirled at a rate of 1400 to 1500 r.p.m. or the equivalent for 10 minutes. The combined volume of water and sediment at the bottom of each tube shall be read and recorded, estimating to 0.1 cc. if necessary. The centrifuge tubes shall then be replaced in the centrifuge, again whirled for 10 minutes, and removed for reading the volume of water and sediment as before. This operation shall be repeated until the combined volume of water and sediment in each tube remains constant for three consecutive readings. In general, not more than four whirlings will be required.

Water and Sediment

7. The combined total volume of water and sediment shall be read on each tube, estimating to 0.1 cc. if necessary. The sum of the two readings shall be recorded as percentage of water and sediment, centrifuge method.

ACCURACY

8. With care and proper attention to details, duplicate determinations of water and sediment by this method should not differ by more than 0.2 cc. provided the centrifuge tubes are accurate and readable to this degree.

Oxidation at High Temperatures

Note: This Method Must Not Be Applied to Used Oils Owing to the Danger of Explosion Due to Moisture or Water Present in the Oil.

Signficance of Test

When petroleum oils deteriorate in service, this deterioration is generally accompanied by oxidation and the formation of oxidation products. In some types of service the possibility of oxidation is not considerable, but in others, such as the lubrication of steam turbines, the ability of the oil to resist chemical change is of prime importance. Accordingly, a method of test that will measure this characteristic is desirable.

The "Sligh Method" consists of subjecting a definite amount of oil to a temperature of 200 deg. cent. in a special flask, from which the air has been displaced and oxygen substituted, for a period of 2.5 hr. The material precipitated from the oxidized oil by petroleum naphtha is a measure of the deterioration of the sample under test.

Oils that have been subjected to oxidizing conditions are usually acidic in nature (organic acids) and if water is brought in contact with such oils, and agitated, undesirable emulsions will be formed.

The steam turbine lubricating system provides opportunity for these conditions to occur when oils are employed which are easily oxidized.

In the selection of oil for steam turbine lubrication a knowledge of the Oxidation Number and the Steam Emulsion Number (providing the viscosity is suitable) furnishes valuable information with regard to possible performance and freedom from sludge formation.

Method of Test

The oxidation value of turbine oils shall be determined by the "Sligh Method" developed at the Bureau of Standards and published in A.S.T.M. Proceedings, Vol. 27, Part 1, 1927, Appendix, p. 461.

PROPOSED OXIDATION TEST FOR MINERAL OILS (SLIGH METHOD)

This method of measuring the resistance of mineral oils to oxidation was developed in the oil laboratory of the U. S. Bureau of Standards. It is the outcome of several years of experimentation with the object of developing an oxidation test which would yield consistent results, which could be precisely specified so that agreement between different laboratories would be possible, and which would not make extraordinary demands upon the operator's time or patience.

It has been taken for granted that the mass of residue precipitated from a petroleum naptha solution of an oxidized oil is a comparative measure of the degree of oxidation of the oil. With this as a basis, various methods of subjecting the oils to definite oxidizing influences have been investigated with this method as the result.

1. The procedure for this method shall be as follows:

(a) Weigh into a clean standard oxidation flask[1] a sample of 10 g. ± O.1.g. of the oil. Displace the air in the flask by oxygen under atmospheric conditions (760 mm. of mercury and 25 deg. cent.) and clamp the slightly greased ground stopper carrying the connection plug into place.

[NOTE: This joint should be gas tight as leakage of oxygen during the test will produce low results.]

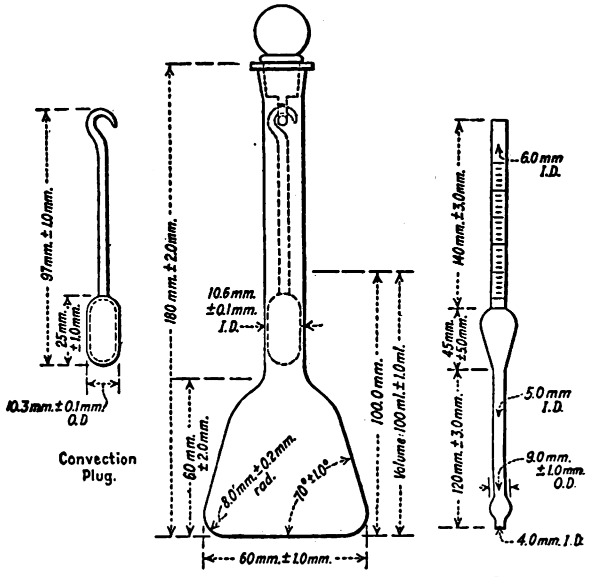

FIG. 12—OXIDATION FLASK AND OIL PIPETTE, A.S.T.M.

---

[1] Standard oxidation flasks and oil pipettes as shown in Fig. 12, are manufactured in Pyrex glass and may be obtained through dealers in laboratory supplies.

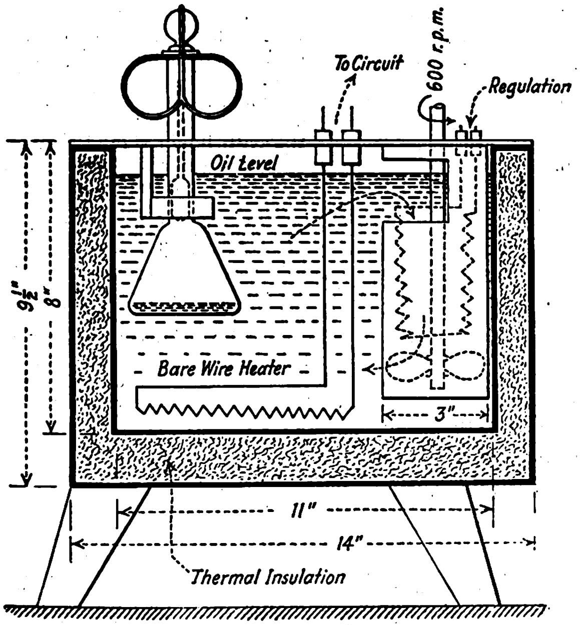

FIG. 13—OXIDATION OIL BATH, A.S.T.M.

(b) Immerse the flask and sample vertically in a well stirred oil bath, Fig. 13, maintained at 200 deg. cent. (392 deg. fahr.) to a point about 1 in. above the body of the flask. Remove after 2.5 hr. at this temperature.

(c) When cool, dilute the oxidized oil to a total volume of 100 cc. with petroleum naphtha. Shake to dissolve the oxidized oil and allow to stand for one hour at a temperature of 25 deg. cent. with a variation of ± 2.0 deg. cent.

[NOTE: The naphtha used should have an end point below 120 deg. cent (248 deg. fahr.), and should be free from unsaturated and cyclic compounds. The naphtha specified in the Tentative Method of Test for Precipitation Number of Lubricating Oils (D 91-21 T)[2] should be used as standard, though any suitable naphtha may be used for the comparative rating of a given series of oils. In general, the amount of precipitates obtained from a given sample of oxidized oil increases with the volatility of the naphtha used.]

(d) Filter and weigh the precipitate. The weight of this precipitate expressed as a percentage of the weight of the sample of oil used and multiplied by 100 is the oxidation number of that sample. Thus, a precipitate of 0.0205 g. (20.5 mg.) from a 10.0 g. sample would be expressed as an oxidation number of 20.5.

The above procedure is thought to be sufficient if followed precisely to insure consistent results. However, the specific procedure followed in the oil laboratory of the U. S. Bureau of Standards is described in detail below as it may serve to call attention to some desirable precautions and conveniences.

APPARATUS

2. (a) *Oxidation Bath*—An oil bath equipped for heating and circulating the oil shall conform to the dimensions shown in Fig. 13. It shall be maintained at a temperature of 200 deg. cent. ± 1 deg. cent. and the circulation should be such that temperature gradients in the bath are negligible. A propeller 2.75 in. in diameter mounted in a 3-in. tube and driven about 600 r.p.m. will give adequate circulation. The bath shall be of sufficient size to accommodate at least six oxidation flasks. A bath 8 in. deep having a capacity of about 3 gal. is suggested. If of a circular form the diameter would be 10 to 11 in. Clamps or supports to hold the flasks in a vertical position shall be provided and a well-fitted cover should be used to reduce the rate of deterioration of the bath fluid and to protect the greased seals on the flasks from overheating. In very warm weather it may be necessary to direct a blast of air, as from an electric fan, across the top of the bath to keep these seals cool. Leakage of oxygen almost invariably results if the stop-cock grease becomes hot enough to flow.

(b) The oil used in the bath should, for safety, have a high flash point and should also have a high resistance to oxidation.

(c) A bath having the construction shown in Fig. 13 should require an input of from 200 to 300 watts to maintain a temperature of 200 deg. cent. Manual or automatic temperature control may be used as desired.

3. *Drying Oven*—The drying oven shall be an air oven in which a temperature of about 105 deg. cent. (230 deg. fahr.) is maintained.

4. *Balance*—The analytical balance shall be sensitive to 0.0001 g. For rough weighing to 0.01 g. it is convenient to reduce the sensitivity and period by attaching a small (2 g.) weight on the pointer. A sensitivity of 1 division on the scale for 0.01 g. permits very rapid weighing of oil samples. The full sensitivity shall, of course, be used in obtaining the weight of precipitates.

5. (a) *Oxidation Flasks*—The oxidation flasks shall be special long-necked Erlenmeyer flasks with the ground glass stoppers and convection plugs conforming to the dimensions shown in Fig. 12. The convection plugs shall be interchangeable in the flasks and serve to render the temperature in the flask independent of the temperature of the room. Convection up and down the neck is also suppressed by their use.

(b) It is essential that the stoppers shall be a good fit in the neck. This may be tested by seating the stopper with a drop of naphtha on the grinding. Under this condition the stopper should seat firmly without shake which may be readily detected by the motion of the thin film of naphtha between the surfaces when a lateral force is applied to the top of the stopper. The stopper clamps (see Fig. 14) shall be bent to shape from the phosphor-bronze spring wire 0.057 in. in diameter (No. 15 B. and S. gage). The half-rings which encircle the flask neck just below the bead shall be cushioned with a wrapping of thread on a short length of soft tubing such as rubber or varnished cambric to avoid localized pressure which might cause breakage of the flasks.

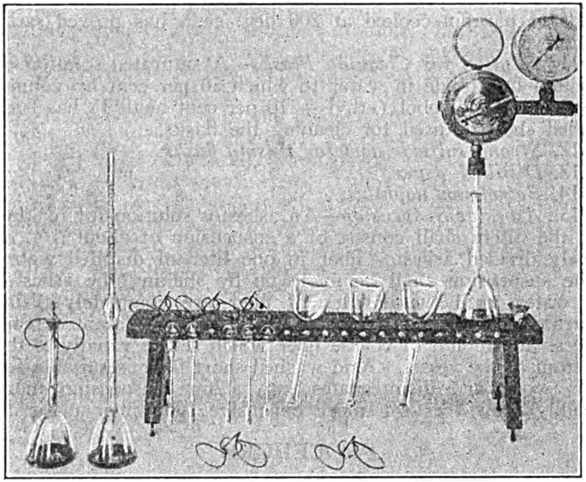

FIG. 14—MISCELLANEOUS EQUIPMENT FOR OXIDATION TEST, A.S.T.M.

[NOTE: This cushioning material is not shown on the clamps in Fig. 14 but should be used. The clamps should exert a total force of about 2 lb. on the stoppers.]

6. *Gooch Crucibles*—Gooch crucibles of the ordinary variety, size No. 3 (25 cc.) of porcelain with perforated bottoms shall be used. These may be marked for identification (see Fig. 15) with chromium oxide and a small amount of borax made up to a creamy paste with water and burned in. The marking may be made on the crucible with a steel pen, allowed to dry in air, and burned in at a temperature of about 1000 deg. cent. with a blow torch or in a furnace.

---

[2] Proceedings, A. S. T. M., Vol. 21, p. 648, (1921); also 1926 Book of A. S. T. M. Tentative Standards, p. 457.

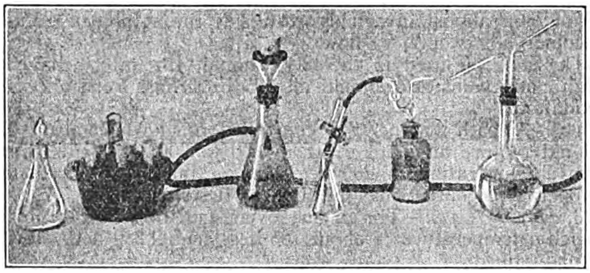

FIG. 15—FILTER SET-UP.

7. *Suction Flask and Accessories*—Fig. 15 shows a convenient filtration outfit. The suction flask "A" shall be connected to the suction system by a rubber tube to which a three-way valve "V" is connected by a glass tee. This valve shall connect to a 300 cc. drexel-form gas wash bottle "B," as shown, which shall be filled with mercury to a depth of about 8 cm. The other valve connection opens to the atmosphere.

8. *Oil Pipettes*—The oil pipettes shall conform to the dimensions shown in Fig. 12 and shall be used in weighing the samples of oil into the oxidation flasks to permit easy adjustment to the desired weight and to prevent soiling of the sides and neck of the flask.

9. *Erlenmeyer Flasks*—Erlenmeyer flasks from ordinary stock should be roughly calibrated and marked for a volume of 100 cc.

10. *Stop-Cock Grease*—Stop-cock grease shall be of medium or hard grade as required to maintain the seal under the operating conditions. A grease made of 72 per cent of petrolatum, 16 per cent of rubber (pure gum), and 12 per cent of paraffin cooked at 200 deg. cent. has proved satisfactory.

11. *Solution for Cleaning Flasks*—A saturated solution of sodium hydroxide in water to which 50 per cent by volume of denatured alcohol (ethyl + 10 per cent methyl) has been added shall be used for cleaning the flasks.

12. *Strong sulfuric acid for rinsing flasks.*

13. *Distilled water.*

14. *Petroleum naphtha.*

15. *Asbestos Suspension*—An asbestos solution for making up the filters shall consist of a suspension of about 6 g. of finely divided asbestos fiber in one liter of distilled water. The suspension shall be made up by shaking the asbestos in water until the bundles of fiber are completely disintegrated. The fine suspension should then be decanted from the small amount of coarse fiber which settles rapidly to the bottom of the vessel. Acid-washed short fiber is suitable for this work and disintegrates into a fine suspension more readily than does the more expensive long fiber material.

PROCEDURE

16. (a) *Weighing of Oil Sample*—The weight of the clean empty flask shall be obtained. A card bearing these weights and the approximate weights of the crucibles posted near the balance will prove a great convenience. Approximately 12 cc. of oil shall be drawn into the oil pipette, the tip of the pipette wiped and the oil transferred to the weighed flask, allowing the oil to drain to a definite point, say till 10 oil drops have been formed. A 10-g. weight shall be placed on the weight pan and a rough balance obtained. The weight of sample is, say, 9.82 g. The pipette shall be replaced in the flask and 3 drops (about 0.05 g. per drop) allowed to drain in. An exact balance should now show 9.95 g., which is within the specified limits (10 g. ± 0.1 g.).

(b) *Filling with Oxygen*—The stoppers of the flasks shall now be slightly greased and the convection plugs attached. A flask shall be brought up over a vertical glass tube through which oxygen (commercial purity as supplied in drums) is issuing downward at the rate of about 2 liters per min. The flask shall be held in this position for about 30 sec. (see Fig. 14) and then removed and the stopper carrying the connection plug quickly put in place, seated and clamped.

(c) The increase in pressure upon heating is largely due to the expansion of the oxygen, as the vapor pressure of lubricating oils is low even at 200 deg. cent., so that with the small necks used a light clamp exerting a total pressure of about 2 lb. should be sufficient.

(d) The flasks shall now be placed in their clips in the bath, which has already been brought to a temperature of 200 deg. cent. The level of the bath liquid should be about 1 in. above the body of the flasks and sufficient space should be left between the flasks and the bottom and sides of the bath for free oil circulation.

(e) After 2.5 hr. at 200 deg. cent. the flasks shall be removed and allowed to cool, and the bath oil washed off in a vessel of gasoline or gasoline-benzol mixture kept for this purpose. The flasks shall then be opened and about 50 cc. of petroleum naphtha added to dissolve the oxidized oil. This solution shall be transferred to a 100 cc. short-necked Erlenmeyer flask, the rinsing from the oxidation flask added, and the solution made up to a total volume of 100 cc. The precipitation flasks shall be corked and set aside to precipitate at a temperature of about 25 deg. cent. for 1 hr.

[NOTE: This precipitation is an equilibrium process and the final state depends upon the temperature as well as upon the nature of the solution. The temperature coefficient of solubility of these oil naphtha solutions is such that, in general, the mass of precipitate is increased by about 1 mg. for each 5 deg. cent. decrease in the temperature of precipitation. Except in precision work, it is not ordinarily necessary to take special precautions to insure the proper precipitation temperature. However, it is customary in the laboratory of the U. S. Bureau of Standards to set the precipitation flasks in a large vessel of water at room temperature and to observe and record the temperature of this water at the time filtration is made. This permits an approximate correction to 25 deg. cent., and guards against rapid changes in temperature.]

After the oxidized oil is transferred to the precipitation flasks the oxidation flasks shall be thoroughly cleaned as described in Section 19.

17. (a) *Preparation of Filters*—The desired number of Gooch crucibles shall be set on a rack above a pan or drain, Fig. 15, and into each shall be poured about 20 c.c. of the asbestos water suspension. This shall be allowed to drain for a few minutes to permit the formation of a thin mat on the bottom of the Gooch crucible and each crucible then sucked dry over the suction flask. The suction valve may be opened wide and the by-pass valve "V" closed to give rapid action. The filter may be washed through with denatured alcohol (90 per cent ethyl + 10 per cent methyl) to hasten the drying, if desired.

(b) The filters shall then be heated in the drying oven for from 30 min. to 1 hr. as required, and allowed to cool in a dessicator, from which they are taken to be weighed when needed.

[NOTE: If the crucibles are slightly warm or if they have become electrified, due to wiping before weighing, erratic weighings will result. No difficulty will be encountered due to atmospheric moisture as neither the filter nor the filtrate takes up moisture readily. Weighings of filters should be taken to the nearest 0.0001 g.]

18. (a) *Filtration*—The weighed filter shall be placed on the suction flask, well seated, and the suction valve set to give a slight bubbling through the mercury by-pass "B," Fig. 15, which should be set to release at a suction of about 8 cm. of mercury.

(b) The clear solution above the precipitate shall now be poured on the filter. A small metal spreader may be used if the filter pad shows a tendency to wash aside. When the precipitate begins to appear, the pouring shall be stopped, the neck of the precipitation flask rinsed into the filter with a stream of petroleum naphtha from the wash bottle.

(c) The oil on the sides of the filter shall now be washed down with a stream of petroleum naphtha and the precipitate carefully poured on. Care should be taken to rinse all precipitate out of the precipitation flasks using a stiff bristle brush to loosen up adherent precipitate. Finally, the precipitate and the filter shall be thoroughly washed with naphtha to remove traces of oil, sucked dry and placed in the drying oven for 15 to 30 min., and when dry removed to cool in the dessicator and the second weighing taken.

19. (a) *Cleaning Flasks*—The oxidation flasks after use shall be filled with a solution of alcoholic caustic-soda and allowed to stand over night or heated for 30 min. in a vessel of water at about 50 deg. cent. and allowed to stand for several hours.

(b) The solution shall then be poured back into its container, the flasks shaken out with clean, coarse washing sand to remove the deposit which the cleaning solution has loosened but not dissolved. After rinsing with tap water, sulfuric acid shall be used to neutralize traces of soda which are active in promoting oxidation. The acid shall then be thoroughly rinsed out with tap water and after a final rinsing with distilled water the flasks set slantwise in rack, not on pegs, to drain and dry; see Fig. 14.

(c) These narrow-necked flasks dry slowly but the process may be hastened, if desired, by heating in the drying oven and inverting the warm flask over a tube through which air is drawn by suction.

(d) This thorough cleaning is essential and shall be performed each time a test is run as traces of oxidized oil remaining in the flask may produce erroneous results in the succeeding test.

The precipitation flasks often show a slight brownish stain which is partially removed upon rinsing into the filter. The mass of this adherent film is negligible as compared to the total mass of the residue.

Precipitation flasks shall be cleaned by rinsing with benzol or carbon tetrachloride followed by petroleum naphtha.

Gooch Crucibles—After the final weighings the filter pads shall be taken out and any stain wiped off with a cloth moistened in benzol or carbon tetrachloride. The crucibles shall be rinsed with petroleum naphtha and may then be made up for the next test.

SOURCES OF ERROR

19. *Oxygen Loss*—A large part of the trouble reported from a number of laboratories regarding this test seem to be attributable to loss of oxygen from the flask during the test. This may be due to a poor fit of the stopper in the neck or the overheating of this point due to inadequate insulation of the top of the oxidation bath.

20. *Breakage of Flask*—Some breakages of the flask at the grinding have been reported. These may be due to poor fit of the stopper, grit on the grinding or more probably to localized pressure of the clamp on the neck or bead.

Erratic results may also be due to imperfect cleaning of the flasks or accidental contamination after cleaning.

DISCUSSION

This oxidation test was designed primarily for the examination of internal-combustion engine lubricants and the conditions of test were chosen with special reference to simplification, reproducibility and acceleration of the tests. Thus, 200 deg. cent. seems to be the highest temperature at which reproducible results may be readily obtained, though a lower temperature may be found more suitable for certain classes of oils.

The use of the mass of asphaltene precipitated from a definite solution of the oxidized oil in petroleum naphtha as a measure of the deterioration of the sample under test seems justified because this precipitate is the product which is largely responsible for the formation of troublesome deposits and "sludges" in service. In addition, the evaluation of this precipitate is fairly simple and has long been in use in oil laboratories.

However, this precipitate is only one of the products of oxidation and it may well be that other products in addition, acidity for instance, may be found to have great influence upon the utility of the oil for certain classes of service.

The test, however, appears to have certain general advantages regardless of the specific conditions of test and the method of evaluation of results which may be found to be useful in particular cases. These advantages may be summed up as follows:

The conditions of test are definitely reproducible and may be varied independently, thus permitting a study of the effects of each factor.

The effects of catalyzers such as metallic oxides or the effects of the oxidation products upon materials with which the oil is in contact in service may be investigated.

The reaction takes place in a closed system and so effects of different atmospheres, air, ammonia and the like, upon the reaction may be noted.

Further, all of the reaction products are available for evaluation and study, and it may thus be possible to work out a complete reaction balance for a given set of conditions. It has been noted that in oxidation substances are formed which have higher molecular weights than the original oil; acids, carbon dioxide and water vapor are also formed.

The quantitative evaluation of these products for particular oils should yield information regarding the effects of methods of refining and treatment upon the stability of the oil.

MANUFACTURERS' STATEMENTS

STATEMENT BY LAMOTTE CHEMICAL PRODUCTS COMPANY

Non-Technical Definition of the "pH" (Hydrogen-Ion) Scale

The principle of making pH measurements by the colorimetric method is based on the fact that various indicators change in color when they are acted upon by solutions of different acidities or alkalinities. Litmus paper is probably the simplest and best known example of an indicator. If litmus paper is dipped into an acid solution, it turns red. If it turns only slightly red, the solution is said to be "slightly" acid. If it turns deep red, however, the solution is said to be "strongly" acid. Similarly, if the paper turns blue the solution is said to be "slightly" or "strongly" alkaline. These are very vague and indefinite terms and their meaning varies enormously, depending largely on the opinion of the worker.

In making pH measurements, definite pH values such as 3.0, 7.4, 9.6, etc., are substituted for the indefinite terms "strongly" and "slightly" acid and alkaline. These pH values can be recorded and can be duplicated at any time.

The degree of acidity or alkalinity of a solution is expressed by the Hydrogen Ion Scale. Instead of being called degrees, as in the case of the thermometer, the units on this scale are called pH values. It is apparent that it is not necessary to know the derivation of the term "degree fahrenheit" in order to determine the temperature of a solution. It is equally true that the worker need not know the meaning of the term "pH" in order to use this method for measuring acidity and alkalinity. On the Hydrogen Ion Scale, a value of pH 7.0 represents neutrality. This means that if the material being tested has a pH of 7.0 it is neither acid nor alkaline.

Thus, any values higher than pH 7.0 denotes alkalinity, the degree of alkalinity increasing as the numbers increase. Analogously, any values lower than pH 7.0 denote acidity, the degree of acidity increasing as the numbers decrease.

It is apparent that if a solution has a pH of 7.6 it is alkaline. If another has a pH of 8.2 it is more alkaline than the one of pH 7.6. It is also clear that acid must be added to a solution of pH 7.6 to bring it to the neutral point of pH 7.0, and that larger quantities must be added to bring it to an acidity of 6.8, 6.0, etc. Similarly, if a solution has a pH of 6.0, it is acid, and it is necessary to add alkali to it in order to bring it to the neutral point pH 7.0, or to an alkaline value such as pH 8.0.

In order that the worker may have some idea of the degree of acidity corresponding to various pH values, it may be stated that a solution which has a pH value of 5.0 is ten times as acid as one with a pH of 6.0. Analogously, a solution of pH 4.0 is ten times as acid as one of pH 5.0. Thps, pH 4.0 indicates an acidity 100 times as great as one of pH 6.0. A similar relationship holds on the alkaline side of the scale. That is, a solution which has a pH of 9.0 is ten times as alkaline as one which has a pH value of 8.0, etc.

As previously stated, litmus is very insensitive partly because it covers such a wide range. In order to make accurate pH determinations it is, therefore, necessary to employ indicators with short ranges, so that the color changes are more distinct.

This means that a number of indicators are necessary to cover the entire pH range 1.2 to 12.6. A complete set of indicators developed to cover this range is shown in the following table:

Name	pH Range	Color Change
Meta Cresol—Purple.	1.2— 2.8	Red—yellow
Bromphenol—Blue ..	3.0— 4.6	Yellow—blue
Bromcresol—Green ..	4.0— 5.6	Yellow—blue
Chlorphenol—Red ...	5.2— 6.2	Yellow—red
Bromthymol—Blue ..	6.0— 7.6	Yellow—blue
Phenol—Red	6.8— 8.4	Yellow—red
Cresol—Red	7.2— 8.8	Yellow—red
Thymol—Blue	8.0— 9.6	Yellow—blue
Nitro—Yellow	10.0—11.6	Colorless—deep yellow
Sulfo—Orange	11.0—12.6	Pale Yellow—deep orange

The actual determination of pH value by the colorimetric method is a very simple procedure. All that is necessary is to add a definite amount of indicator to a definite amount of the water sample (10 c.c.) and compare the color against color standards corresponding to the indicator used.

This control method has been so widely adopted that the pH values which should be maintained in connection with boiler water conditioning has been very definitely determined.

Technical Discussion of Hydrogen Ion Concentration and the Derivation of pH Values

According to the theory of electrolytic dissociation, all liquids, of which water is a constituent, contain free H and OH ions. When the number of H ions exactly equals the number of OH ions, the solution is said to be neutral. If the number of H ions exceeds that of the OH ions, the solution is said to be acid. Conversely, if the solution contains an excess of OH ions, it is said to be alkaline.

It is well known that acidity is due to the presence of H ions in a solution, the acidity increasing as the number of H ions increases. Strong acids are those which are highly dissociated in solution to give a large number of H ions. Weak acids are those which are but slightly dissociated in solution and, therefore, give relatively few H ions. For example, hydrochloric acid (HCl) is a strong acid and acetic acid is a weak one. In titration, 10 c.c. of N/10 HCl and 10 c.c. of N/10 acetic acid will, of course, each require 10 c.c. of N/10 NaOH for neutralizations. The number of H ions in N/10 HCl is, however, almost 70 times as great as the number of H ions in N/10 acetic acid. It is readily seen that the H ion concentration is not determined by simple titration. Since it is the H ion concentration and not total acidity which is the controlling factor in the majority of chemical reactions, the importance of making pH determinations is apparent.

Pure distilled water will conduct an electric current to a very slight degree. This shows that a very small proportion of the water is dissociated into H and OH ions. By the mass law.

$$\frac{\text{Concentration of H Ions} \times \text{Conc. of OH Ions}}{\text{Concentration of Undissociated } H_2O} = \text{a Constant}$$

Since the amount of undissociated water is relatively large, it can be taken as a constant, and the above equation becomes:

$$\text{Conc. of H Ions} \times \text{Conc. of OH Ions} = \text{a Constant}$$

By electrical conductivity measurements, this constant has been found to be 1/100,000,000,000,000 or 10^{-14} at 21 deg. cent. Since in pure distilled water the number of H ions is equal to the number of OH ions, each must have a concentration of 1/10,000,000 or 10^{-7}.

This method of expressing H ion concentration is very inconvenient and clumsy. Sorensen suggested the use of the term "pH," the pH value being the logarithm of the reciprocal of the hydrogen ion concentration. Thus,

$$pH = \log \frac{1}{(H+)}$$

Just as an acid solution is said to be normal when it contains 1 g. of ionizable hydrogen per liter, so a solution is said to be normal with respect to hydrogen ions when it contains 1 g. of ionized hydrogen per liter. Since

$$pH = \log \frac{1}{(H+)}$$

is the reciprocal of the normality of H ions in a solution, the pH value can also be defined as the logarithm of the denominator expressing the normality of H ions such as N/10, N/100, N/1000, etc.

This method of expressing H ion concentration has now been generally adopted. In the case of pure distilled water, in which the H ion concentration is 0.0000001 or N/10,000,000 the pH value would be the log of 1/0.0000001 or of 10,000,000, which is 7.0. This value 7.0 is the neutral point on the pH scale.

It will readily be seen that pH values below 7.0 such as 6.0, 5.0, etc., will denote acidity, the degree of acidity is increasing as the numbers decrease. For example, if a small amount of HCl is added to pure distilled water which has an H ion concentration of 10^{-7} or a pH value of 7.0, the acid will dissociate into positive H ions and negative Cl ions. The total number of H ions in the solution will be greater than 10^{-7}, and the solution will therefore be acid. Suppose the H ion concentration is found to be N/1,000,000. The pH value will be the log of 1,000,000, which is 6.0. Similarly, if the H ion concentration is N/100,000, the pH value will be 5.0, etc. It should be remembered that, since we are dealing with logarithmic values, a solution having a pH value of 6.0 contains 10 times as many H ions as one having a pH value of 7.0. Similarly, a solution of pH 5.0 contains 100 times as many H ions as one of pH 7.0.

Since by the law of mass action

$$\text{Conc. of H Ions} \times \text{Conc. of OH Ions} = \text{a Constant,}$$

it is apparent that as the H ion concentration increases the OH ion concentration must decrease, and vice versa. Even in a strongly alkaline solution there are, however, some H ions, and for the sake of simplicity it is advisable to express both acidity and alkalinity in terms of pH values.

From the fact that neutral water has an H ion concentration of N/10,000,000, it is apparent that an alkaline solution must contain a smaller number of H ions. Let us assume that, by adding a small amount of sodium hydroxide to pure water, we decrease the H ion concentration to N/100,000,000. The pH value of this solution will be 8.0. Similarly, if the H ion concentration is reduced to N/1,000,000,000, the pH value would be 9.0. This shows why all values higher than 7.0 indicate alkalinity, the degree of alkalinity increasing as the numbers increase. It should be remembered here also that a solution of pH 9.0 contains 10 times as many OH ions as one of pH 8.0.

It is therefore seen that the pH value is an absolutely accurate measure of the degree of acidity or alkalinity of a solution. By making these determinations, definite values are obtained which can be recorded and which can be duplicated exactly at any time by the same or different workers. We are, therefore, not dependent on such vague and meaningless terms as slightly acid or alkaline, moderately or strongly acid, or alkaline, etc.

The exact meaning of H ion concentration and pH values, and the derivation of the latter, can be made clear by a few concrete examples. A N/10 solution of hydrochloric acid is one which contains 3.65 g. of HCl or 0.1 g. of ionizable H per liter. Electrical conductivity measurements have shown that at 18 deg. cent. 91.4 per cent of the HCl is dissociated. This means that 91.4 molecules out of every 100 do not exist as molecules, but are split up into H and Cl ions. The remaining 8.6 per cent exist as molecules. If the HCl were completely ionized, the N/10 solution would contain 0.1 g. of H ions per liter. Since, however, only 91.4 per cent is ionized, it contains

$$0.1 \times \frac{91.4}{100} = 0.0914 \text{ g. of H ions per liter.}$$

The normality of this solution with respect to H ions is

$$\frac{1}{0..0914} = N/10.94$$

The pH value of N/10 hydrochloric acid is therefore the logarithm of 10.94 or 1.0.

A N/10 solution of acetic acid also contains 0.1 g. of ionizable H per liter. Electrical conductivity measurements show, however that at 18 deg. cent. it is dissociated only to the extent of 1.36 per cent. Hence the hydrogen ion concentration is

$$0.1 \times \frac{1.36}{100} = 0.00136 \text{ g. per liter.}$$

This is equivalent to a N/735 solution of H ions. The pH value of N/10 acetic acid is therefore the log of 735, which is 2.86.

Since the hydrogen ion concentration of N/10 HCl is 0.0914 g. per liter and of the acetic acid 0.00136 g. per liter, the hydrochloric acid contains almost 70 times as many hydrogen ions as the acetic acid.

The following table will give the worker some idea of the relationship between the total acidity and pH value of a few common acids and bases. The pH values have been given for N/10 solution and are rounded off to the nearest 0.1, as this is sufficiently accurate for general work. Thus, the above value for acetic acid, pH 2.86 is given as 2.9 in the table:

Acids	pH Value	Bases	pH Value
HCl	1.0	$C_6H_5NH_2$	7.8
H_3PO_4	1.5	$NaHCO_3$	8.4
CH_3COOH	2.9	$Na_2B_4O_7$	9.2
H_2CO_3	3.8	NH_4OH	11.3
H_3BO_3	5.2	Na_2CO_3	11.6
C_6H_5OH	6.0	$NaOH$	13.1

From the above discussion it will readily be seen that if the solutions encountered were only solutions of known pure acids and alkalis, the pH value could be calculated from the titration values and ionization constants. This is, however, seldom the case, as the solutions normally contain relatively indefinite quantities of other substances, and usually a number of unknown impurities. Many of these materials have what is known as "buffer action," which means that considerable quantities of acid or alkali can be added to them without changing their pH value.

STATEMENT BY THE LEEDS AND NORTHRUP COMPANY, PHILADELPHIA, PA.

pH Indicator

The Leeds & Northrup No. 7654 pH indicator is designed especially for pH measurements with the quinhydrone calomel electrodes, and because of reliability the set-up is better than any other now available. The instrument is compact and easily operated. The standard cell and galvanometer are included with the case, the working battery being connected externally. A photograph of the assembled indicator and cell is reproduced in Fig. 16.

A schematic diagram of the pH indicator is shown in Fig. 17.

Binding posts marked "Q" and "C" provide connections for the quinhydrone and calomel electrodes respectively. The indicator is calibrated in millivolts with a range from — 400 to + 100 millivolts, which corresponds to pH 1 to 9 (with the quinhydrone-calomel electrodes). The guaranteed accuracy of the instrument is 2.5 millivolts or approximately 0.04 pH. The galvanometer affords a sensitivity of 0.05 millivolt, or about 0.01 pH. The quinhydrone electrodes cannot be used where the pH is more than 8.5 or 9.0.

The calomel electrode, which serves as a reference potential, is prepared in the usual manner by placing in a suitable vessel mercury, calomel and potassium chloride solution (saturated KCl is generally used). The quinhydrone electrode is a gold, or unplatinized, platinum electrode, immersed in the test solution to which a few milligrams of quinhydrone have been added.

With the electrodes properly connected the procedure in making pH determinations may be outlined by the following steps:

1. Standardize potentiometer current by depressing "S C" key and rotating the knurled rheostat knob behind the gal-

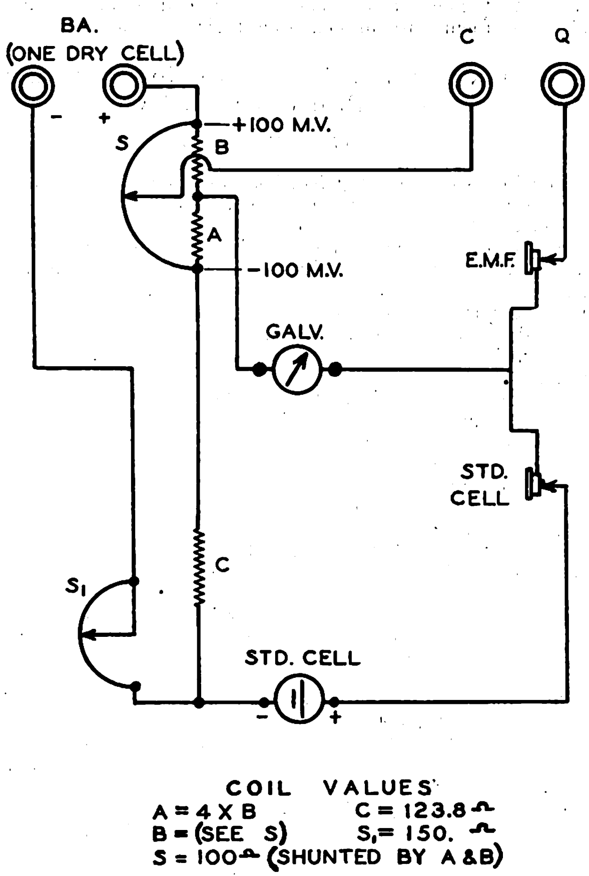

FIG. 17—SCHEMATIC DIAGRAM L. AND N. No. 7654 pH INDICATOR.

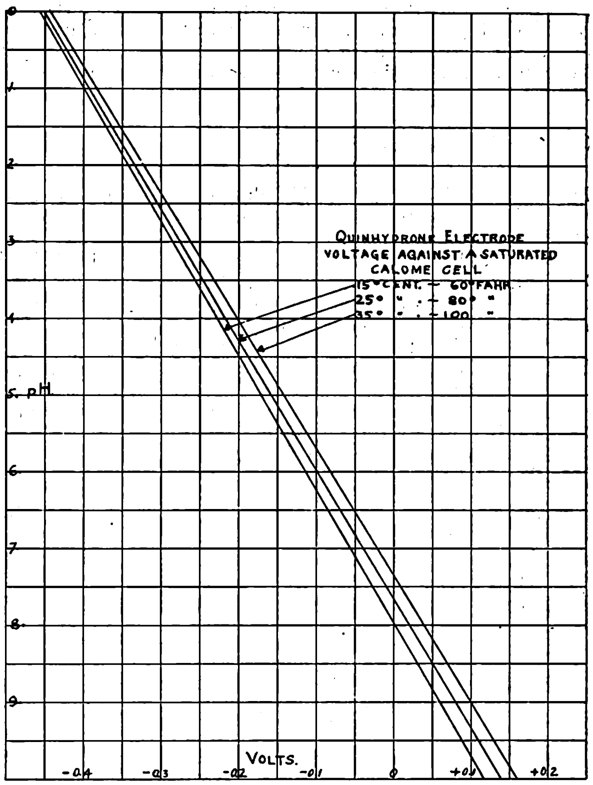

FIG. 18—pH VOLTAGE CHART—QUINHYDRONE ELECTRODE, L. AND N.

vanometer until the galvanometer needle balances at zero. This step in the procedure is required daily unless a new dry cell is being used, in which case more frequent standardization is required.

2. Add a few milligrams of quinhydrone to the test solution in the beaker in which the electrodes have been placed, stir, depress "E.M.F." key and rotate knurled "MILLIVOLTS" knob until galvanometer balances at zero.

3. Read temperature of solution and refer this, together with millivolt reading, to the pH voltage chart—Fig. 18—for the pH value.

With very little experience a pH determination can be made in less than a minute.

Specific Conductance

The specific conductivity (Mho-ohm) bridge is a special form of an A-C. Wheatstone bridge for operation on any commercial lighting circuit and so arranged that the readings of the bridge are given in conductivity directly.

This bridge is a development which may be of interest in certain applications where it is desired to measure conductivity directly, rather than in terms of resistance with corrections for cell constant.

The new bridge is shown in Fig. 19 with the combined temperature and cell compensator in the front of the case. A clearer view of the compensator is shown in Fig. 20.

It is necessary to use with this bridge a cell having a constant within certain limits. The bridge can then be calibrated to read directly in conductivity by adjusting the compensator.

A connection diagram for the bridge is shown in Fig. 21.

COAL AND ASH HANDLING

During the past year probably the most notable development in the handling of coal and ash has been the introduction of the molten slag method of removing pulverized fuel ash from the furnace. Two member companies report the successful adoption of such a system of ash removal.

For stoker-fired boilers one member company gives complete maintenance costs for various types of ash hoppers and gates.

Two statements are offered showing new coal handling equipment.

Two member companies offer short statements on the commercial disposal of ash.

A complete test is reported on a new coal distributor spout, and a statement is made regarding its operation.

The use of the drag scraper system for storing coal is steadily growing.

Statements from five manufacturers are given, covering, among other items, a motor-operated ash gate and a new vestibule-type ash hopper.

Problems to be studied by the Committee are: Further developments in handling pulverized fuel ash as molten slag; the removal of ash dust from flue gas by electrical precipitators and other methods; the commercial disposal of ash; and new designs of coal and ash handling equipment.

A brief bibliography is included.

MEMBER COMPANY STATEMENTS

STATEMENT BY THE PUBLIC SERVICE ELECTRIC & GAS COMPANY

Ash Hoppers and Gates; Maintenance Costs

"The following data on various types of ash hoppers and gates are taken from the Essex, Marion, Burlington, Perth Amboy and Camden generating stations.

Essex Station

"At Essex Station the ash hoppers are of steel construction with brick lining and are of four different designs, the general features of which are as follows:

"Considerable difficulty was experienced with the ash hoppers under the eight 13,720 sq. ft. B. & W. boilers forming units 1 and 2. Each hopper is divided into two sections, each equipped with only one gate. It was found that the slope of the walls was not steep enough and the mouth opening was too small. As these boilers are not equipped with clinker grinders, large clinkers often hang on the side walls, choking the mouth, preventing the rapid removal of the ash and making the labor of dumping an expensive item. The mouth of the hopper was originally constructed with a heavy cast-iron throat piece, but repeated heatings and quenchings broke these castings, destroying the alignment of the gate slides and hindering the operation of the pneumatic gates.

"After ten years of service, in 1925, it was decided to change the design of the hopper mouth, eliminating as much metal as possible from contact with the ash and quenching water. This was done by riveting an angle iron to the hopper steel work to carry the load of brick lining above, by raising the channels supporting the gate-operating mechanism up to the hopper mouth and by sliding the gate on angles riveted to the channels. The intermittent sprinkling system was replaced by continuous sprinklers. Since that time the gates have operated satisfactorily and their maintenance has greatly decreased.

"The four 12,780 sq. ft. B. & W. boilers, comprising unit No. 3, were equipped with clinker grinders when installed. The ash hoppers were of the same general type as units 1 and 2, that is, there was a two-section hopper to each boiler. The walls of these hoppers, however, were made steeper and two gates, separated by a peaked division wall, were installed in each section, making four gates per boiler in the place of two per boiler, as previously used. The same trouble with the cast-iron throat pieces was experienced, and in addition there was a tendency for the ash to catch on the division wall between the two gates in each section and hinder its removal.

"After eight years of service, in 1926 the throat pieces were removed and a mouth design similar to redesigned units 1 and 2 was installed; continuous sprinklers replaced the intermittent type.

"The ash hoppers of unit No. 4, consisting of four 12,780 sq. ft. B. & W. boilers, were further improved by removing all internal division walls, making one large hopper per boiler, increasing the number of gates to five, and bringing the slope of the side walls nearer to the vertical. The throat pieces soon gave trouble and were replaced by the new design after five years' service, and continuous sprinklers were installed.

"Units No. 5 and 6, each consisting of four 12,980 sq. ft. B. & W. boilers, have been in service for over three years with practically no trouble. Since the original installation, which consists of one large hopper per boiler, no changes have been made. The hopper walls are very steep and the ends are vertical. Each hopper is equipped with six pneumatically operated gates.

"In general, it may be said that the ash hopper troubles at this station have been eliminated and the maintenance costs decreased by the removal of as much metal as possible from contact with the ash, and by using continuous sprinklers in place of the intermittent. Table I gives the maintenance costs of ash hoppers and gates for the boiler units at Essex Station.

Marion Station

"At Marion Station the ash hoppers are of three different designs, the general features of each being explained later.

"If the boilers are operated at ratings under 200 per cent, the linings in the hoppers last as long as the hoppers, but when operated at higher ratings for any great length of time, large clinkers are likely to drop into them, and in breaking these clinkers damage is done to the brick lining. As long as the brickwork is in good condition the outer castings of the hopper will not crack. An intermittent quenching system is used, operating only when the ashes are dumped from the grates. Because of this fact, during

the past five years, common brick has been used when it became necessary to reline the hoppers. The results obtained were the same as when fire brick were used and at a lower cost. Another reduction in ash hopper maintenance consists in concreting all iron beams supporting the hoppers, thus preventing the rapid deterioration of the beams through the action of salt water and gases. Before the beams were concreted, hoppers often had to be taken down simply to replace a few supporting members.

Type 1

"In this group there are two hoppers and two gates for each boiler. Each hopper is made up principally of four sides and a bottom plate, all of which are of cast-iron, as are the gates themselves. The gates are pivoted at one point by means of a bolt and, in opening, travel along a supporting rail. The life of this type of hopper is from ten to fifteen years. During the life of the hopper the only parts necessary to replace are the bottom plates and the gates, which, not being protected by brick lining, are subject to rapid changes in temperature due to the hot ash and cold salt water and, therefore, crack. Both are replaced every five years without taking the boiler out of service. After the gates have been in service for a year or so they sag a little, due to the weight and heat of the hot ashes. This sag causes a considerable loss of draft and is remedied by taking up on the guide rail.

Type 2

"In this group there is one large hopper to each boiler, and each hopper has four doors which slide on guides. These doors are operated by hand, as are the gates of Type 1. The hopper is supported by steel girders at top and bottom. The sides of this type of hopper are of ⅜ in. sheet steel, whereas the bottom plates and gates are cast iron. The life of these hoppers is from ten to fifteen years. The parts that require replacing during the life of the hopper are the bottom plates, the gates and the beams upon which the lower part of the hopper rest. All of these are replaced every five years. The bottom plates and gates crack due to rapid temperature changes and from the effects of salt water and gases. The lower supporting beam becomes weakened from these causes and sags, thus throwing the guides out of line so that the gates will not close tightly, causing a loss of draft which necessitates the replacement of the beam and the lining up of the door guides. The boiler has to be taken off the line to replace the bottom plate, a gate or a beam. Replacement of one bottom plate or gate necessitates the removal of the side supports, the bottom supports and the other bottom plates and gates. To install a new support beam on the side requires the shoring up of the whole hopper.

Type 3

"This type of hopper, used on both underfeed and overfeed stokers, is of sturdy construction, with the hopper and gates of cast-iron. One large hopper and four sliding gates are furnished for each boiler. These gates are hand lever operated. The life of these hoppers is about fifteen years. The guides for the gates wear badly, necessitating a replacement to prevent too great a loss of draft on the underfeed stokers. The gates need to be replaced about every five years. The bottom castings or the gates can be replaced without taking the boiler out of service; yet, on account of the heavy construction the charges on this work run a little higher than on Type 1, but less than on Type 2.

"Since the separate costs on each of the types mentioned are not available, the costs of maintaining ash hoppers and gates on fifty 6000 sq. ft. B. & W. boilers are given in Table II.

Burlington Station

"At this plant there are four 6000 sq. ft. B. & W. boilers, four 6130 sq. ft. Edge Moor boilers and two 14,180 sq. ft. B. & W. boilers. The eight smaller boilers have one hopper of steel plate construction, brick lined, to each unit. The cast-iron gates are of the clam-shell type, one to each boiler. They are hand operated, the lever lifting one side and this side lifting the other three segments. On the two 14,180 sq. ft. boilers, the hoppers, one to each boiler, are also of the steel-plate construction, brick lined, but the gates, of which there are six per boiler, are cast iron of the sliding type, operated by compressed air. The hoppers and gates under the two larger boilers were installed in 1923, and, to date, excluding the air cylinders, there have been no repairs or maintenance. The ashes are quenched by water sprays during and immediately after dumping, and the pits are emptied as soon as possible. As there is a much larger opening on the hoppers of the larger boilers, they are, of course, much more desirable. The manual operation of the gates on the smaller boilers and the prying loose of clinkers through the narrow gate opening sometimes require strenuous effort. The maintenance costs for the eight small boilers are shown in Table II.

Perth Amboy and Camden Stations

"At Perth Amboy the eight 6000 sq. ft. B. & W. boilers are each equipped with one divided, sheet-steel hopper lined with fire brick. The bottom ends and gates are of cast-iron. The gates are pivoted at one end by a bolt, and in opening travel along a supporting guide rail; they are manually operated by a lever and move in a horizontal plane. After the gates have been in service a year or so, they sag a little due to wear and the weight and effect of hot ashes, but this is remedied by taking up on the guide rail. All the iron beams that support the hoppers are faced with fire brick as protection from the hot gases. The intermittent system is used to quench ashes.

"The original hoppers were in service from 1911 to 1917 and 1918, when they were rebuilt. In 1922 four of these hoppers were again renewed and the others repaired. They were all renewed in 1924. The average life of the frame and gate is five years, while the brick lining is repaired when necessary and the iron work painted once a year. Over a period of seven years the average cost of maintaining the ash hoppers and gates at this plant has been 3.455 cents per gross ton of coal burned, the coal consumption over this period being 344,711 tons.

"At Camden Station there are six 5000 sq. ft. Altman Taylor and two 6000 sq. ft. Edge Moor boilers. The hoppers are of the single type, one to each boiler, and are of cast-iron. The gates, one to each hopper, being of the same type as those just described, are subject to the same troubles. The hoppers are lined with fire brick and their average life is about fifteen years, while the bottom castings and gates give about five years' service. All iron beams supporting the hoppers are protected by a layer of fire brick laid up in Portland cement and have not been renewed in twenty-two years. The intermittent sprinkler system of quenching is also used at this plant. The maintenance cost of ash hoppers and gates at Camden Station, over a period of eight years, averages only 0.524 cents per gross ton of coal burned; however, during this period only 245,505 tons of coal were consumed."

STATEMENT BY THE CONSOLIDATED GAS, ELECTRIC LIGHT & POWER CO.

Commercial Disposal of Pulverized Fuel Ash

"The furnace ash is collected in the ash pits located below the water-screen tubes. These ash pits are equipped with Allen-Sherman-Hoff gates and water jet system, sluicing the ash into a pit outside the plant, where, at the present, it is removed by a crawler crane equipped with a clamshell bucket. Such soot as collects in the soot hoppers of the boilers is run through pipes to the sluiceway and is mixed with the furnace ash. The contents of the clamshell bucket are dropped into a dump truck, hauled to a nearby site, and used for fill purposes.

"So far we have found no use for this ash from which a satisfactory income can be derived. We will soon be unable to use the nearby site, and our ash-disposal costs will be increased. The ash is not very suitable fill material, if the made ground is called upon to sustain any appreciable weight, and, for this reason, there is no demand for this use.

"From investigations we have made, its use in making Portland cement is about the only one of promise, though in our case, because of the small amount produced, this cannot be considered. We have experimented with building blocks similar to those known as 'cinder blocks,' but the characteristics as to strength, etc., were far inferior to the ordinary cinder blocks.

"On the basis of tons of dry refuse, computed from coal and ash analyses, we realize an average return of approximately 34 cents per ton for ash from stoker-fired plants, this figure being obtained by dividing total money received from sale by tons produced. It should be noted that not all ash produced is sold, some being hauled to a nearby dump. However, in our case the amount of money received for ash is favorable to the stoker-fired plant, and is of such an amount that it may affect the choice of equipment, depending, of course, upon how close the costs are to a balance"

STATEMENT BY THE DETROIT EDISON CO.

Commercial Disposal of Ash

"The stoker ash, or cinders, from each of The Detroit Edison Co.'s stoker-fired plants is sold in the local market. The credit resulting from the sale of this ash amounts to approximately 90 per cent of the total cost of ash disposal. Average costs and credits of ash disposal for the combined stoker-fired plants for the year 1927 are given in Table III.

TABLE III

ASH DISPOSAL COSTS—STOKER-FIRED PLANTS

Item	Cost in Cents per Ton of Coal Burned
Operating costs	4.6
Maintenance costs	1.4
Total costs	6.0
Credit from sale of cinders	5.4
Net cost of ash disposal	0.6

"The most common commercial uses of stoker ash are as an aggregate for concrete roof and floor slabs, and as the body of cinder blocks used in building construction. It has been used experimentally as a constituent in a furnace refractory patching material and also in a road-surfacing material, but these cannot as yet be considered commercial uses.

"Although the question of ash disposal may often be of minor importance in the selection of the fuel-burning equipment, it may, on the other hand, have a very decided influence.

TABLE IV

ASH DISPOSAL COSTS—PULVERIZED FUEL PLANTS

Item	Cost in Cents per Ton of Coal Burned
Operating costs	1.2
Maintenance costs	1.0
Total costs	2.2
Credits	0
Net cost of ash disposal	2.2

"In Table IV are given the costs of ash disposal for pulverized fuel plant for the year 1927.

"Comparison with Table III shows that, while the operating and maintenance costs of ash disposal are considerably lower for the pulverized fuel equipment, this advantage is more than offset by the credit resulting to the stoker-fired equipment from the sale of cinders. It should also be noted that there is no market up to the present time for the fine ash produced by pulverized fuel furnaces. The question of ash disposal assumes its greatest importance, then, in the choice of fuel-burning equipment, when the proposed plant location prohibits 'dumping' the pulverized fuel ash near at hand, and where there is, at the same time, an assured market for stoker ash."

FIG. 1—COAL HANDLING SYSTEM, WATERSIDE STATIONS, NEW YORK EDISON CO.

STATEMENT BY THE NEW YORK EDISON COMPANY

New Coal Handling System

"The new coaling system at the Waterside Stations, Fig. 1, was installed to unload and handle coal direct from ocean-going colliers of large capacity, in addition to the existing barge unloading facilities.

"The coal is unloaded by two traveling towers of 350 tons per hr. capacity each, is crushed and delivered to the belt conveyor 'A,' from which it is taken by other belt conveyors for distribution to Stations No. 1 and 2. These outside conveyors are completely housed. The sampling and weighing is done en route.

"The existing unloading facilities for Station No. 2 have been arranged with short belt conveyors which connect to the new system.

"From conveyor 'C' coal can be transferred, by a chute, to barges for transportation to the other stations of the New York Edison and Allied Companies system."

STATEMENT BY THE IOWA RAILWAY & LIGHT CORPORATION

Coal Handling in a Small Plant

"At the Boone, Iowa, plant of the above company are installed four 4100 sq. ft. and one 5200 sq. ft. Edge Moor boilers, all fired by chain grate stokers, and 6000 kw. of generating capacity. The coal-handling equipment consists of an 18 in. apron feeder of 25 tons capacity at 15 ft. per min. taking coal from the hopper under the railroad tracks and delivering it to a 10 in. by 8 in. continuous bucket elevator with a lift of 48 ft. and a capacity of 25 tons at 100 ft. per min. This elevator discharges the coal directly into a 4 ton, driving weigh larry, which in turn feeds the stoker hoppers, with an extension capacity of two tons each. The entire outfit is electrically driven. This scheme has the advantage of rather low cost for a small plant, and with the driving weigh larry coal weights can be obtained to give a check on evaporation and plant performance. The entire layout is shown in Fig. 2."

STATEMENT BY THE BUFFALO GENERAL ELECTRIC CO.

Removing Molten Ash by the Hydro-Jet System

"Among the innovations in the installation of the pulverized fuel boilers at the Charles R. Huntley Station, where comparatively low-fusion-ash coals are burned, was the hydro-jet system of removal of molten ash.

"All four of the new boilers erected during the recent extension of the station were of the B. & W. cross-drum type, 44 tubes wide and 11 tubes high, containing 12,500 sq. ft. of boiler heating surface. Each boiler is provided with a separate economizer. The furnace under the first boiler included a well 8 ft. square and 11 ft. deep, sunk into a furnace floor that was 17 by 25 ft. and averaged 12 ft. 9 in. to the bottom row of boiler tubes. The sides of this well were formed by 3¼ in. tubes on 6 in. centers covered on the fire side with solid calorized-steel Bailey blocks. At the top of the well these tubes were bent outward at an angle and ran uncovered through the furnace to the headers on the outside of each wall. The well floor was constructed of carborundum tile covered by blocks of the same material. The bottoms of these tile formed the roof of a plenum through which the secondary air entered the furnace, flowing in back of the well tubes. No water tubes were installed in this floor. Burners were set in each wall halfway between the furnace center line and right-hand adjacent wall, in such a manner as to create a rotating effect when in operation.

"It was expected that the cyclonic effect in the well would keep it free from ash, which would drop out as the gas expanded into the main furnace above the well. However, it soon became apparent that bare blocks would not withstand the high combustion rate of 1,100,000 B.t.u. liberation per cu. ft. of well volume, equivalent to 62,000 B.t.u. per cu. ft. of combined furnace and well volume.

"Subsequent changes in the well blocking, in which the calorized-steel blocks were replaced with refractory-faced Bailey blocks and the sloping well tubes above the well covered with clay tile, served to increase the furnace temperature to the point where the ash became molten and dropped directly or ran from the clay tile into the well. This increased temperature reduced the carbon carry-over and improved combustion generally. That portion of the slag which ran down the clay tile banks on the sloping tubes continued downward into the well, flowing on the face of the wall. Upon reaching the floor, the slag formed a pool, remaining in the molten state because of the high temperature of the furnace above and the absence of cooling tubes below. This fluid could be tapped through a hole in the bottom of the well, but the problem was to find a satisfactory means of disposal after tapping.

TABLE V

COAL (DRY BASIS)

	Per Cent
Fixed carbon	53.29
Volatile matter	34.66
Ash	12.05
Sulphur	2.85

Fusing point of ash, about 1950 deg. fahr.

Sulphur trioxide (SO_3)	1.80
Undetermined	0.25

"The analyses of coal and slag are given, together with a few of the characteristics of the slag, in Table V.

"When solid, the slag had a very low coefficient of heat transmission, which made it a good heat insulation for the well floor, as the lower part of the slag solidified due to the passing of secondary air beneath the bottom of the well. This characteristic also added to the problem of handling, as will be discussed later.

"At a high temperature and below its melting point, the slag was tough and viscous, like molten glass. When cool it was a dense black solid, often with a coppery opalescence at a fracture; it was hard enough to cut glass and weighed approximately 200 lb. per cu. ft. When running from the slag spouts into the open air, the outer part of the stream congealed and the flow continued through the center, forming a tube or pipe, one of which is shown at C in Fig. 3, in which are shown: A, a solid block of slag; B, mineral or slag wool; C, the slag tube formation, and D, the granular slag from the sluice discharge.

"The original method of slag disposal, pending a solution of the ash-handling problem, was to allow it to run onto the floor each night before shutting the boiler down, and remove it the next day with a pick and shovel gang. This method was mussy and, of course, impractical, involving a high labor cost, and the concrete floor on which the hot slag was dropped chipped away due to the heat. The slag would spread around the floor, working outward from a point underneath the spout, resembling a bed of molten volcanic lava. A water hose turned upon it served only to chill a skin at the surface, the interior remaining in the molten state and flowing onward, bursting through the chilled skin at various places.

"While the status of the problem was as set forth, three additional pulverized fuel-burning boilers, of a different furnace design, were placed in service. These had furnaces 15 ft. 7 in. square with walls going straight up at both ends and expanding on the sides to a width of 25 ft. 8 in., at an elevation of 7 ft. 6 in. above the furnace floor. The well floor line was 30 ft. from the lower boiler tubes. The furnace walls were of the refractory-faced Bailey block construction and had the same tube spacing as the boiler previously described, there being, however, greater cooling surface and greater furnace volume. The well floor was supported on steel girders and consisted of a steel plate, over which were placed two layers of firebrick, covered with 6 to 8 in. of burned dolomite. These furnaces operated at a heat release of 37,000 B.t.u. per cu. ft. of total furnace volume, which is equal to 236,000 B.t.u. per cu. ft. below the top of the burners.

"The ash in these boilers assumed the same molten form as in the previous boiler, but the slag spouts, being closer to the floor, made the solution more difficult. Numerous suggestions were offered as to the best method of disposal, such as refractory-lined larry cars, handling the ash in the molten state, pouring the slag into water-filled dump cars direct from the furnace, and various combinations of sluicing and elevating into the cars. But the spouts on the boilers last installed were too low to permit an ordinary car to be placed beneath them, and, although handling molten ash in such cars is everyday practice around blast furnaces, it was considered too hazardous for installation in the boiler plant.

"While the new furnaces were in construction, experiments were made of dropping the slag directly from the furnace into a concrete buggy filled with water. Strangely, no explosion occurred and there was little sputtering. The slag stream formed its own insulating tube to the bottom of the buggy and built up as if there were no water on top of it. The sheet metal casing on the bottom of the buggy became red hot long before the surface of the water showed any signs of boiling. When the bucket was half full of slag, it was rolled to one side, and some fifteen minutes later it was emptied and the interior of the slag was still red hot.

"Sluicing was then tried out by placing an 8 ft. length of 12 in. channel iron, sloped at an angle of about 30 deg., under the spout of the original boiler and placing two ¾ in. water nozzles at the top, so as to sweep the channel clean. The lower end discharged into an ash car. These tests on sluicing led to observations that were of great value in

FIG. 5—SLAG WATER PUMP, BUFFALO GENERAL ELECTRIC CO.

arriving at the final solution. The slag stream was broken into small pieces by the mechanical force of the jets, and these pieces in turn tended to shatter into smaller pieces, owing to the rapid chilling effect of the water made possible by the exposing of greater surface areas per unit volume of slag. These facts indicated the necessity of using comparatively large volumes of water and were responsible for hydro-jet handling.

"A test equipment was then installed under one boiler by the Allen-Sherman-Hoff Co. This consisted of three primary jets which threw parallel streams, forming, owing to the close spacing, a water table within a cast-iron disintegrating chamber. On this the molten slag fell directly, being broken into small pieces and partly chilled at this point. Falling from here into a U-shaped cast-iron trough, the slag was carried crosswise of the building with the aid of two carrier jets for a distance of approximately 10 ft., and still further chilled in the process, owing to the additional cold water. This flow hit a cast-iron smashing plate, where it was turned at right angles into another U-shaped cast-iron trough running lengthwise of the building and discharging at a distance of approximately 50 ft. in the adjoining yard. Two additional carrier nozzles, working in tandem, were placed at the head end of this run. The results from this test equipment exceeded expectations. The slag was deposited in a fine granular state at the discharge of the chute.

"Steps were, therefore, taken to provide a permanent installation, but, owing to the fact that the best point for permanent disposal was about 1000 ft. from the boilers, it was found necessary to pump the mixture of slag and water after discharge from the hydro-jet system. The layout decided upon is shown in Fig. 4. To meet this requirement a pit was designed into which the sluices discharged. Two special manganese steel pumps, each of approximately 760 g.p.m. capacity, were provided for this service, and a cast-iron suction pipe run into the discharge pit. Fig. 5 shows one of these pumps. All elbows in the suction and discharge piping are of manganese steel. One pump is intended for a spare, as both are connected in parallel to the same discharge main, which is of 6 in. steel pipe running along the side of the building and out across the adjacent land to the point of disposal. The pipe is pitched to make it self-draining and is not insulated. Fig. 6 shows this discharge in service. Note that the material discharged spreads over a wide area instead of forming a pile beneath the pipe, as had been expected.

"In operation this system has worked out as satisfactorily as on test, although it has been found desirable to increase the pressure at the nozzles from 100 to 140 lb. in order to handle a higher rate of slag flow. These rates of flow are uncertain, being dependent upon the length of time the boiler is in service, the furnace temperature and the prior day's firing condition.

"The tapping of slag from these four boilers requires the services of two men for a period of one to three hours daily. The quantity of water pumped depends more upon the time required than upon the actual weight of slag removed, as it is necessary to provide enough water during the early stages of tapping to care for the maximum flow that may be encountered, and this is a somewhat indefinite quantity on account of the standby peak load operation of the station. The slag may vary from a mere trickle to a 6 in. diameter stream, coming fastest just after the flow is established and decreasing in amount as time progresses. Fig. 7 shows the slag spout in action. When the flow decreases, the pressure at the jets may be throttled down as experience dictates.

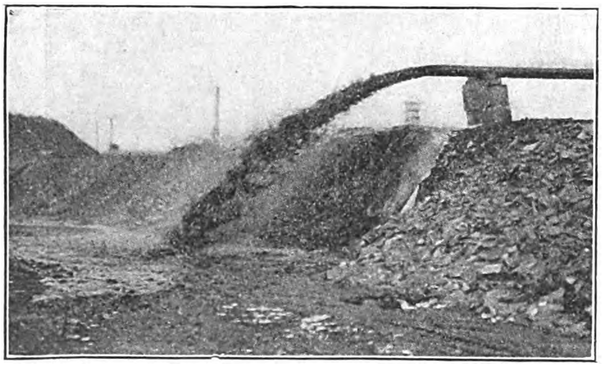

FIG. 6—DISCHARGE FROM SLAG DISPOSAL SYSTEM, BUFFALO GENERAL ELECTRIC CO.

"As the slag is highly abrasive, renewable wearing plates were placed in the sluiceways at all right-angle turns and were also placed in the concrete receiving pit to take the direct impingement of the slag-bearing water.

"It is remarkable that this installation, which is the first to be designed for handling molten slag from boiler furnaces by the hydro-jet system, should have proved so successful from the start. Had not the low furnace floor levels of the boilers last installed made the handling of this slag in the molten stage by means of slag cars extremely difficult, this happy solution of the problem might not have been found."

STATEMENT BY THE PENNSYLVANIA-OHIO POWER & LIGHT CO.

Handling Pulverized Fuel Ash as Molten Slag at Toronto Power Station

Slag Bottom No. 5 Boiler
